Vermont’s Wildlife Action Plan

November 22, 2005

Approved by the US Fish & Wildlife Service 11/22/2005
I. Acknowledgments
Just over a year ago we asked local, state and national agencies, non-governmental organizations, sportsmen, conservationists, academics, land managers and other wildlife experts to join together in the development of an all-state, all-species wildlife conservation strategy. The response to this ambitious challenge was an extraordinary and unprecedented outpouring of collaborative effort resulting in Vermont's Wildlife Action Plan (formally the Comprehensive Wildlife Conservation Strategy). We thank the many participating Conservation Partners (Table 1-1) for responding to the call despite already busy schedules. Moreover, our appreciation goes out to the individuals serving on the eight technical teams (Table 3-1) charged with the nitty-gritty details of conducting species and habitat assessments, integrating the varied and complex needs of many wildlife species and crafting a report for all Vermonters interested in wildlife conservation.

We gratefully acknowledge the help of the International Association of Fish and Wildlife Agencies, and in particular Dave Chadwick, who provided tireless and invaluable 24-7 assistance, coordination and encouragement to Vermont and the other states and territories. We are grateful to the US Fish & Wildlife Service, particularly Colleen Sculley and the rest of the staff at the Region 5-Federal Assistance office, for their ongoing guidance and support.

We thank Vermont's congressional delegation who helped create the opportunity for this Wildlife Action Plan (WAP) and for establishing and maintaining the State Wildlife Grants program that funds WAP development and implementation. State Wildlife Grants together with the other federal wildlife conservation funding programs are vital to keeping common species common.

We humbly note that our goal would have been unattainable without a solid foundation—the rich legacy of Vermont's wildlife conservation history—the observations, stories, data, research, planning efforts, conservation, education and wildlife-recreation programs, institutions and traditions established and nurtured by those passionate about wildlife and Vermont's natural heritage over the past two centuries.

Finally, to all those furry, finned, feathered, scaled, slimy and shelled creatures—the charismatic megafauna and the enigmatic microfauna—that so fascinate and enrich our lives and economies, we look forward to a bright and healthy future together in the Green Mountain State.

Funding
Funding for the development of the Vermont Wildlife Action Plan was provided by the State Wildlife Grant Program, Vermont Fish & Wildlife Department, voluntary contributions to Nongame & Natural Heritage Program Wildlife Tax-Check-off and License Plate fund, and the many organizations, agencies, businesses and individuals who volunteered their time and expertise.

Recommended citation
Dear Fellow Vermonters,

It is my pleasure to present to you this report: *Vermont's Comprehensive Wildlife Conservation Strategy* (CWCS). It was prepared by the Vermont Fish & Wildlife Department in collaboration with representatives of more than 60 local, state and national partner organizations and agencies. The CWCS represents the beginning of a historic conservation effort -- never before has Vermont undertaken such a comprehensive review of its wildlife.

Wildlife is important to Vermont and Vermonters. Wildlife is integral to the functioning of the ecosystems upon which we all depend, and two-thirds of Vermonters take part in wildlife-associated recreation. These Vermonters, along with tourists coming to Vermont to enjoy our wildlife, add close to $400 million to our economy annually.

We have a rich heritage of wildlife conservation going back more than 225 years to the appointment of our first game wardens in 1779. In 1864, George Perkins Marsh of Woodstock changed the way people around the world thought about land and land stewardship with his book *Man & Nature*. In the early 1900's, sportsmen played pivotal roles in the return of Vermont's wildlife icon the white-tailed deer, and later moose, beaver and salmon. And this year, all Vermonters can join me in celebrating the recovery of the common loon, peregrine falcon, and osprey to the point where they have been removed from the state’s endangered species list.

The Comprehensive Wildlife Conservation Strategy marks the start of a new era in wildlife conservation, one where we can keep common species common. Furthermore, the CWCS complements my Clean & Clear Action Plan for Lake Champlain and the recently released Northern Forest Land Council 10th Anniversary Forum's Final Report: *Recommendations for the Conservation of the Northern Forest* to conserve the public and private forest lands and improve the economic viability of communities within our northern forests.

Together, these efforts support healthier wildlife populations and Vermont’s reputation for a high quality of life and conservation of natural resources.

Sincerely,

The Honorable James Douglas
III. A User’s Guide to Vermont’s Wildlife Action Plan

Vermont’s Wildlife Action Plan is a statewide, all-species conservation strategy to conserve wildlife and vital wildlife habitat before species become more rare and more costly to protect. The Action Plan is chock full of recommended actions, wildlife and habitat information and helpful resources for implementing conservation at many scales—from the very local to the statewide and beyond. All people, organizations, businesses and agencies (local, state and federal) are encouraged to take part.

Though the Action Plan contains an enormous amount of information, and it may seem easy to get lost in the details, the following information will help you stay on track:

1) **Introduction and Overview:** Regardless of how you intend to apply the information in the Action Plan (whether for research, education, grant writing, or on-the-ground conservation and management) begin by reading chapter one, the introduction, and the first half of chapter two, the Vermont Overview. These sections provide a science-based foundation for understanding the issues involved in addressing wildlife needs and puts conservation actions into a broader perspective to enhance the value, effectiveness and impact of your conservation work.

2) **Assess your goals:** Use the Wildlife Action Plan to identify how your or your organization’s mission and goals relate to the needs of wildlife and wildlife habitat identified in the Action Plan. Questions to consider include: What strategies, in what part of the state, could I or my organization best implement? Which would provide the greatest long-term benefits?

For example do you prefer to work locally (e.g., maintaining and improving wildlife habitat on your own land), within your community (e.g., incorporating wildlife conservation into your town plan), within a landscape or watershed (e.g., maintaining or improving the connectivity of a river and its tributaries), or at the statewide level (e.g., reducing the economic pressures on landowners that drive land conversion and fragmentation or working to reduce acid precipitation and mercury deposition into Vermont waters).

- **If you are interested in conservation and management of a particular property or habitat type:** As an example, if you are developing a management plan for your woodland property in northern Vermont, you might be interested in the habitat and community types most likely to occur there and the Species of Greatest Conservation Need (SGCN) generally found in each. Thus, you might want to “enter” the Action Plan at page 4:35 (for landscape forests and major waterways) or appendix B (for other habitat types). There you’ll find habitat type descriptions, SGCN lists, descriptions of the problems impacting those habitat types as well as priority conservation actions, and potential partners funding sources.

- **If you are interested in the conservation a particular species or species group:** “Enter” the document at page 4:12 for overviews of species by taxonomic group (e.g., birds, fish, invertebrates, mammals, reptiles and amphibians). Go to Appendix A to for detailed information about each Species of Greatest Conservation Need (SGCN). For example, if you are interested in conserving reptiles and amphibians you can go straight to page 4.30, if you are particularly interested in wood turtle conservation go to appendix A5 for the wood turtle Species Assessment Report.

- **If you want to address the overarching problems impacting wildlife across the state and region:** “Enter” the document at chapter 1:9-Statewide Themes for Action. Here you will find actions designed to address the big picture issues and problems impacting all of Vermont’s wildlife and wildlife habitat and that are most effectively addressed at the state, regional/national and international levels. For example, habitat loss along migration routes and the economic pressures that drive habitat fragmentation.
3) **Focus resources at conservation opportunity areas**: These are the lands and waters where the likelihood of successful conservation is strongest and the conservation needs of SGCN would best be met. For example, conserving large forest blocks, connectivity between blocks and connectivity of waterways is a foundational theme of Vermont's Wildlife Action Plan. To identify these opportunity areas use data sets available from the Fish & Wildlife Department and others such as contiguous forest blocks, wildlife linkage habitat, conserved lands, wildlife management areas, species richness and state significant community occurrence. Areas falling outside of conserved lands may be particularly vulnerable and provide opportunities for conservation.

Recommended actions for these areas include, where appropriate, providing technical assistance to landowners and community planners, maintaining and expanding financial incentives to landowners, supporting programs to retain open space and minimize sprawl and poorly planned development, utilizing permitting processes such as Act 250 to address critical habitat considerations, and acquiring critical habitats in fee title or easement.

**Additional Considerations**

**Recognize the complexity of habitat management**: By its nature, managing habitats can positively affect some species while negatively affecting others. This is to be expected, and land managers have long wrestled with how best to balance the needs of multiple species and habitats for a variety of conservation and economic uses. There is no single “right” way to manage lands—just different ways resulting in different outcomes. It is often beneficial to approach such complexity by looking beyond a specific property and examining how a project fits into the larger landscape. Try also to incorporate not only ecological opportunities but also economic issues, social needs, and political factors.

**The Wildlife Action Plan is a guidance document**, not a regulatory one. It provides a menu of actions for conserving Vermont's wildlife; some actions may be more or less appropriate at any given place or point in time.

**Integration with other plans**: Finally, as comprehensive as it is, the Wildlife Action Plan is not without limitations. For example, it focuses only on wildlife. Additional work is required to integrate the Action Plan with other natural resource conservation and management plans, recreation plans, forest management plans, transportation plans and town plans to name just a few.

**Additional Resources for Action Plan Implementation**

**Implementation Partners and Funding**: A list of potential partners and funding sources can be found in each habitat summary in the Action Plan. Summaries begin on page 4:35 (landscape forests, landscape waterways and shorelines) and appendix B (for other habitat types).

**Conserving Vermont’s Natural Heritage: a Guide to Community-Based Planning for the Conservation of Vermont’s Fish, Wildlife and Biological Diversity**, available from VFWD is specifically designed to help towns plan for and conserve their wildlife [www.vtfishandwildlife.com/library.cfm](http://www.vtfishandwildlife.com/library.cfm).

**Wildlife Habitat Incentives Program** (WHIP), a partnership between the Natural Resources Conservation Service and VFWD, provides technical and financial assistance to landowners to create and enhance wildlife habitat on their lands. Contact 802-241-3700 or fwinformation@state.vt.us

**Landowner Incentives Program** (LIP): a voluntary program of VFWD funded by the US Fish & Wildlife Service, LIP provides cost-share assistance to private landowners to protect, enhance, and restore habitat for rare, threatened, and endangered species. Contact 802-241-3700 or fwinformation@state.vt.us

**Landowner's Guide to Managing Wildlife Habitat** will be available from the VFWD in early 2007. Contact 802-241-3700 or fwinformation@state.vt.us to check on its status.

**Wildlife Action Plan Coordinator**: 802-241-3652, jon.kart@state.vt.us

L. Plans & Planning Processes Impacting Vermont's Wildlife
Congress requires that each state complete a Comprehensive Wildlife Conservation Strategy (CWCS) by October 1, 2005 if it wishes to remain eligible for State Wildlife Grant funds. There are eight congressionally required elements that each CWCS must address to be approved. Congress designated the Director of the US Fish & Wildlife Service (USFWS) to make approval determinations. The USFWS assembled a team of USFWS personnel and representatives from state fish and wildlife agencies and the International Association of Fish & Wildlife Agencies under the title National Advisory Acceptance Team (NAAT) and charged this group with reviewing each CWCS and making recommendations to the USFWS Director regarding CWCS approval.

According to USFWS guidance documents supplied to states, the NAAT “believes it must make an affirmative finding that all of the eight required elements are satisfactorily fulfilled in order for an “approval” recommendation to be made to the Director of the U. S. Fish and Wildlife Service.”

This document is provided to help NAAT reviewers understand how Vermont addressed each of the eight congressionally required elements for a CWCS and where that information can be found in the report. It begins with an overview of how the report is organized and is followed by the eight elements and specifics as to where information satisfying the element can be found in the CWCS.

**Report Development & Organization**

Vermont took a linear approach to developing its CWCS (fig IV-1). We began by gathering stakeholders, experts and other agencies, organizations and individuals interested in wildlife conservation to finalize the development process and staff CWCS technical teams. Technical teams assessed the state’s wildlife populations and then selected Species of Greatest Conservation Need (SGCN). For each SGCN the teams then delineated habitats, identified problems, research and monitoring needs and crafted conservation strategies. The SGCN were then assigned to one or more of 120 habitat categories, aquatic and natural communities and landscapes. These were then organized into 24 major habitat categories. Summaries of the status of each major habitat category were then developed. Statewide strategies and major themes for action were then identified to address those problems that impact many SGCN and habitats. Finally, a plan for the development of a statewide wildlife monitoring and adaptive management program was created.

Though development of this CWCS followed a bottom-up arc from individual species and populations to state and region-wide problems and solutions, its presentation in this report follows a different path. A user-friendly format, that includes five main chapters and 17 appendices, was selected to first provide readers with context, a big-picture view of wildlife conservation in the state, before diving deep in to the specifics of more 300 SGCN. Additionally, because we anticipate that most users of this 1,000-page document will only read sections of it there is some redundancy in the report. Reviewers will find information to help complete their assessment in the locations noted in Table IV-1.

---

1 **Acknowledgement:** We thank the CWCS developers in Michigan and North Dakota for sharing their CWCS reviewer guides which we have adapted here, and the USFWS Region 5 Federal Assistance staff for their support and assistance.

2 **CWCS is the Action Plan:** Comprehensive Wildlife Conservation Strategy was the working title of the Wildlife Action Plan during its development. The CWCS name was changed to Wildlife Action Plan after receiving federal approval on 11/22/2005.
Development of Vermont’s CWCS

1) **Team Building**: Conservation Partners assembled, methods developed, technical teams selected [3:1-7]

3) **Species Assessment Reports**: developed for each SGCN/Invertebrate Group detailing distribution, habitat, problems, research needs and conservation strategies [A1-A5]

4a) **Vegetation Associations**: SGCN are associated with one or more of 120 habitats, communities, landcovers and landscapes [4:35-40 for rationale and categories, A1-A5 for associations]

4b) **Overviews** summarize species’ needs by group (birds, fish, invertebrates, mammals and reptiles & amphibians) [4:12-34]

5) **Habitat Organization**: The 120 habitats, communities, landcovers and landscapes were grouped into 24 major categories [4:35-40]

6) **Habitat Assessment Summaries** developed for the 24 major categories [Landscapes: 4:41-80. Habitats and communities: B:7-86]

7) **Statewide Strategies**: Solutions to overarching problems and needs impacting many SGCN and habitats statewide [1:9-12]

8) **Monitoring, Implementation, and CWCS Review & Revision** [5:1-18]

**Fig 1: Development of Vermont’s CWCS** (Locations beginning with a letter (e.g., “B”) refer to appendices. Appendix “A” contains subsection A1 through A6, one each of the six wildlife taxa examined in the CWCS (e.g. A3:1-6 refers to pages one through six if of appendix A3)
Table 1: Organization of Vermont’s CWCS Report (Locations beginning with a letter (e.g., “B”) refer to appendices. Appendix “A” contains subsection A1 through A6, one each of the six wildlife taxa examined in the CWCS (e.g. A3:1-6 refers to pages one through six if of appendix A3)

<tr>
<td>IB. The Strategy includes information about both abundance and distribution for species in all major groups to the extent that data are available.</td>
<td>A1-A5:all, A.3all</td>
<td>Abundance is noted by State rank &amp; distribution by biophysical region and 8-digit watershed on the first page of each Species/Invertebrate Group Assessment Report. Abundance and distribution data came from NNHP* databases and was augmented by technical team experts. A distribution narrative is also included in the Species/Group Reports. Due to the dearth of data on invertebrate species, invertebrate SGCN are treated by taxonomic and habitat groupings rather than individually. Research needs for each SGCN and SGCN Group are detailed in the Research &amp; Monitoring section of each Species Assessment Report. A plan-wide data gathering monitoring program is outlined in chapter 5.</td>
</tr>
<tr>
<td>IC. The Strategy identifies low and declining populations to the extent data are available.</td>
<td>3:9-10, A1-A5:all, 1:1 (for rank definitions)</td>
<td>VT’s CWCS focused on low and declining populations. Our SGCN list includes federal and state threatened and endangered species, species ranked S1 and S2, and species identified by our technical team experts, partners and scientific literature. SGCN with low populations are identified with a State Rank of S1 (very rare) or S2 (rare) in the Conservation Assessment section of each Species Assessment Reports. The “Regionally Rare” field provides an indication of rarity in the Northeastern US and adjoining Canadian provinces based on regional and national research, BBS routes, other monitoring and consensus within technical teams. Declining populations are noted in the “State Trend” field of the Species Assessment Reports (see Conservation Assessment section). This field records population trends as “Stable,” “Fluctuating,” “Declining,” “Increasing,” or “Unknown.” In many cases “unknown” was selected because of knowledge gaps. The “Assessment Narrative” field provides details where available. Research and monitoring needs are identified for species whose population trends are unknown or poorly known in the Research &amp; Monitoring section of each Species Assessment Report.</td>

<td>1D. All major groups of wildlife have been considered or an explanation is provided as to why they were not (e.g., including reference to implemented marine fisheries management plans). The State may indicate whether these groups are to be included in a future Strategy revision.</td>
<td>3:9-10 A2 4:20-23 A3</td>
<td>VT’s CWCS process considered all major groups of wildlife including, birds, fish, herptiles, invertebrates, mammals, and plants. There are no marine environments with or adjacent to Vermont’s borders. Several anadromous and catadromous fishes are on the VT SGCN list. Appropriate references are included in the Species/Invertebrate Group Assessment Reports for these species. Our knowledge of VT invertebrate is the most limited of all taxa. Research designed to augment our knowledge of invertebrates is included in the Invertebrate Overview and Invertebrate Group Reports.</td>
</tr>
<tr>
<td>IE. The Strategy describes the process used to select the species in greatest need of conservation. The quantity of information in the Strategy is determined by the State with input from its partners, based on what is available to the State.</td>
<td>4:3-8 A6:1-4 3:9-13, 4:1-2 3:11, 4:12-34 3:11, 4:20-23 A3:all</td>
<td>List of VT's wildlife Species of Greatest Conservation Need List of VT's plant Species of Greatest Conservation Need See chapter 3 for selection procedure details. In general, expert input was incorporated through our CWCS technical teams (six Species Teams, Integration Team and Conservation Strategy Review Team). Additional input was solicited from Conservation Partners during Partner meetings and through individual and group correspondence. Taxon specific selection procedures: Species Teams (technical experts for each of the six taxa listed above) selected SGCN based on criteria and guidance developed by our interdisciplinary Integration Team. There was some variation between teams in the threshold used for selection as SGCN (e.g., the herpitile team was the most conservative in selecting SGCN and the mammal team selected the most SGCN based on the need to address data gaps). This being Vermont’s first CWCS our priority was not to ensure parity in numbers across taxa but rather to ensure that experts within each taxon were in accord regarding the species selected. The sheer number of invertebrate species in VT (15,000-36,000) combined with our lack of knowledge of invertebrate biology and life-histories limited invertebrate SGCN selection. Whereas SGCN in other taxa are generally those species about which we know least, invertebrate SGCN are generally those we know best. Future CWCS directed research and surveys will help expand our knowledge of this taxon.</td>

<tr>
<td>4A. The Strategy identifies how conservation actions address identified threats to species of greatest conservation need and their habitats.</td>
<td>C:7-10</td>
<td>Vermont’s CWCS is a strategic document rather than an operational one and therefore focused on conservation strategies, not actions. We have been as explicit as possible in developing and describing conservation strategies while at the same time strategies are intentionally broad, directional, and nonspecific so as not to constrain our selection of actions for implementing strategies. Actions will be developed in the coming months and years during operational planning by the Fish &amp; Wildlife Department and conservation partners. Generally, the connection between the problems and conservation strategies identified in the CWCS are intuitive and self-evident (e.g. habitat threatened by encroaching development would be targeted through a suite of strategies including technical assistance to developers and municipal planning authorities, conservation easements and efforts to increase funding for land acquisition). Strategies are included to address immediate localized problems as well as broader, diffuse stressors and problems that may cause or exacerbate the localized problems (e.g. riparian habitat restoration to improve stream water temperatures and regional efforts to address climate change). Strategies are primarily voluntary and incentive-based.</td>

<td>5:16-17</td>
<td>Ongoing outreach efforts will help inform and involve the public in CWCS implementation and revision. Effective implementation of VT’s CWCS requires ongoing collaboration and coordination with the public. This is stressed throughout the document. The review and revision process will follow the same process used in the development of the CWCS and the public will again be encouraged to participate.</td>
</tr>
</tbody>
</table>

References

VI. Executive Summary

Development of Vermont’s Wildlife Action Plan (WAP) formerly the Comprehensive Wildlife Conservation Strategy) began in January of 2004. Completion of a WAP by October 1, 2005 is a requirement of the federal State Wildlife Grants (SWG) program. The goal of both the State Wildlife Grants program and the WAP is to prevent wildlife from becoming endangered through early, strategic efforts to conserve wildlife and habitat. SWG provides funding and the WAP provides the strategic guidance. Since 2001, Vermont has received or become eligible for more than $3 million in State Wildlife Grant funds.

This is an historic effort. Never before has Vermont undertaken such a comprehensive review of its wildlife. Moreover, every state and territory in the nation is also developing Action Plans. Combined, this is the largest wildlife conservation effort in the US—ever. Wildlife biologists, ecologists, sportsmen and other conservationists, business leaders and state and federal agencies representing more than 60 entities have signed on as Conservation Partners to work with the Vermont Fish & Wildlife Department (VFWD) to create Vermont's Wildlife Action Plan.

This report is the result of extraordinary effort. Employing a rigorous science-based process using the best available existing information WAP technical teams of VFWD staff and Conservation Partners assessed the status all of Vermont's birds (268), fish (94), mammals (61), reptiles and amphibians (42) and many, many groups of invertebrates ranging from mussels, to beetles, to butterflies (estimates of Vermont invertebrate diversity range from 15,000 to 36,000 species).

Following Congressional requirements, the WAP focuses on Species of Greatest Conservation Need (SGCN)—wildlife with declining populations; wildlife that are threatened or potentially threatened; and, wildlife that are so little known in the state that experts cannot yet ascertain their status. Congress further required that each WAP include the following eight elements:

1. Identification of the distribution and abundance of SGCN
2. Descriptions of the location and condition of key habitats
3. Descriptions of key problems and research needs for SGCN and their habitats
4. Prioritized conservation strategies
5. Monitoring plans for species, habitats and conservation actions
6. A process to review and revise the WAP at intervals not to exceed ten years
7. Coordination with other wildlife and land management plans
8. A public involvement process.

Identification of Species of Greatest Conservation Need began in May of 2004. By September 2004 technical teams had selected 143 vertebrates, 191 invertebrate and 577 plants as Species of Greatest Conservation Need. (Note that plants are not eligible for SWG funds, but our hope is that conservation of wildlife SGCN will benefit the plants).

From September 2004 through May 2005 technical teams completed element numbers two through seven above and an interim review of conservation strategies (a.k.a. the reality test) by the Conservation Strategy Review Team occurred in January and February of 2005. Review of the WAP by Agency of Natural Resources commissioners, conservation partners and the general public ran from April through July of 2005.

Problems and Solutions
The problems most frequently identified as impacting SGCN are not new concepts to those concerned about wildlife conservation, they include:

- Information needs and data gaps critical to conservation success
- Loss of habitat (from conversion, degradation, fragmentation and lack of needed successional stages in appropriate juxtaposition)
- Impacts of roads and trails
- Pollution and sedimentation
- Invasive species
- Climate change

As a wildlife conservation guide for the entire state—not just the Vermont Fish & Wildlife Department—the WAP includes some strategies that almost any individual or organization can implement. The most common strategies proposed here to alleviate problems impacting SGCN also aren't new: they include conducting habitat restoration, providing education and technical
assistance to landowner and land managers, providing financial and economic incentives and encouraging wildlife-compatible resource use.

Moreover, the recommendations in this report underscore the need for proactive, cost-effective conservation efforts and increased collaboration, coordination and sharing of data and expertise among all those interested in wildlife conservation. The WAP and its recommended strategies help realize these needs by:

- Providing a common conservation vision to guide state and federal agencies as well as sportsmen’s and non-profit conservation organizations.
- Putting existing land and resource management and conservation needs into a broader context, providing recognition for the contributions that landowners and land managers are already making towards a long-term conservation strategy.
- Building a reliable, science-based data set to provide a “big picture” view (biophysical region and statewide) of Vermont’s wildlife resources to establish current conditions and to measure changes into the future. These data will allow state agencies to work with the public and private sector more effectively.
- Identifying areas where conservation activities will provide the greatest benefit to cost ratio (thereby increasing the effectiveness of limited conservation resources).
- Allowing use of existing programs to more effectively provide incentives or technical assistance to private landowners for voluntary actions to conserve natural resources on private lands and identify the need for additional landowner incentive or technical assistance programs.

Finally, a monitoring program will collect new data and provide an ongoing assessment of the impact and effectiveness of conservation strategies. This information along with regular communication and coordination with conservation partners will serve as the backbone of a adaptive management program to fine-tune conservation strategies and ensure that Vermont’s Wildlife Action Plan will remain a vital road map for wildlife conservation efforts.
The Future of Wildlife Conservation

State Wildlife Grants funding comes at a critical time. The traditional funding source for wildlife conservation at the state level has been sportsmen. Hunting, fishing and trapping licenses and taxes on their gear account for nearly 80% of Vermont's wildlife conservation funds. But the pressures on wildlife have changed and increased in intensity since these funding programs began in the early decades of the 1900's. Today, these funds, most of which are dedicated for game and sportfish species, are stretched thin as the Fish & Wildlife Department addresses new issues and problems such as development and Act 250 reviews, pollution, invasive species and overabundant wildlife. Furthermore there are new and expanding constituencies interested in wildlife and putting pressure on wildlife including hikers, bird watchers, and off-road vehicle users.

The State Wildlife Grants program is not intended to replace sportsmen's dollars. Rather, it will take some of the weight of conservation funding off the shoulders of sportsmen and broaden our capacity to conserve wildlife.

The task of conserving our Species of Greatest Conservation Need is challenging but we know success is possible from our history with wildlife conservation successes such as the wild turkey, white-tailed deer, moose, common loon, fisher and peregrine falcon. Conserving wildlife is in all our best interests. It means reducing the potential imposition of regulatory requirements on Vermont businesses and communities that come with threatened and endangered species listings. It means healthier ecosystems upon which we all depend. And it means a Vermont rich in wildlife which we can all enjoy.

The Wildlife Action Plan and State Wildlife Grants dollars mark the start of a new era in wildlife conservation, one where we can keep common species common.
Vermont's Wildlife Action Plan

Major Conservation Partners.....................................................................7
Statewide Themes for Action......................................................................9
1. Introduction

These are exciting times for wildlife conservation. All across the country, state fish and wildlife agencies are completing a Wildlife Action Plan. New funds and new initiatives are advancing a long history of conservation success.

Vermont is noted for its beautiful juxtaposition of woodlands and farms, streams and ponds—not to mention Lake Champlain and the Green Mountain chain. Fish and wildlife resources are an integral part of the Vermont experience and quality of life for Vermonters. Deer, moose, wild turkey, and geese are thriving and offer sustainable hunting and viewing opportunities. In recent years, loon, osprey, peregrine falcon populations have recovered allowing for their removal from the state threatened and endangered species list. And, many of our waters teem with outstanding fishing opportunities. The landscape and the wildlife attest to the state's meaningful conservation ethic. Vermont's Wildlife Action Plan offers an opportunity for measured engagement, by all Vermonters, in addressing new challenges, filling in knowledge gaps, and implementing management programs to keep common species common thus preventing future need to place species on threatened and endangered species lists.

Mandate, Mission and Strategic Focus

The Vermont Fish & Wildlife Department is specifically charged with promulgating rules, through the Fish & Wildlife Board, enforcing those rules and procedures, and conducting programs that implement the following policy statements.

"The inhabitants of this State shall have liberty in seasonable times, to hunt and fowl on the lands they hold, and on other lands not enclosed, and in like manner to fish in all boatable and other waters (not private property) under proper regulations. (Vermont Constitution, Chapter 2, Article 67)."

"It is the policy of the state that the protection, propagation, control, management and conservation of the fish, game, and fur-bearing animals in this state is in the interest of the public welfare, and that safeguarding of these valuable resources for the people of the state requires a constant and continual vigilance (10 V.S.A. Section 4081)."
The Department's mission is “the conservation of all species of fish, wildlife, and plants and their habitats for the people of Vermont.” The Department’s dedicated professionals enforce laws, manage Wildlife Management Areas, conduct species-specific research, restoration and management actions, issue licenses, grow fish, and provide educational and outreach services. Three of the Department’s planning goals are:

Conserve, enhance, and restore Vermont’s natural communities, habitats, and species and the ecological processes that sustain them.

Provide a diversity of fish- and wildlife-based activities and opportunities that allow the safe and ethical viewing, regulated harvesting, and utilization of fish, plant and wildlife resources consistent with the North American model of fish and wildlife conservation.

Maintain safe fish and wildlife based activities and limit harmful human encounters with fish and wildlife species and provide general public safety service incidental to primary fish and wildlife enforcement duties.

Throughout its 100-year history, many of the Department’s initiatives focused on game species, in part because of constituent interest, as well as the user-pay system of funding fish and wildlife conservation through license sales and excise taxes on hunting and fishing equipment. As our mission statement suggests, the scope of conservation challenges facing the Department extends beyond species which people choose to harvest.

**Problem and Need**

Historically, there have been dedicated funds available for game and sportfish species as well as Threatened and Endangered species. Unfortunately, there has not been a dedicated revenue stream supporting management for the vast majority of wild animals that do not fall within either category. For example, 269 species of birds are found in Vermont. However, only about 30 of these are hunted and only a handful (e.g., common loon, osprey, peregrine falcon) have had recovery funding.
The full status of many species is unknown in Vermont. There are many species for which very little population or distribution data exist including most reptiles, amphibians, small mammals, stream fish, and invertebrates, including insects and crustaceans. In 1985, the Nongame and Natural Heritage Program was established within the Fish and Wildlife Department. Both an income tax check-off and a conservation license plate have been important revenue mechanisms for addressing wildlife diversity management and species recovery planning generating approximately $250,000 per year, but still not sufficient to adequately meet needs.

Vermonters Care about Wildlife

Wildlife is very important to the people of Vermont. Almost anyone you talk with has a story to tell about deer hunting, hummingbirds in the garden, or geese winging south.

The 2001 National Survey of Fishing, Hunting, and Wildlife Associated Recreation conducted by the U. S. Fish and Wildlife Service documented that 67% of Vermonters went fishing, hunting, or wildlife watching. Vermont ranked second, only behind Alaska in participation (US Dept of Interior). This same survey estimates that $386 million was spent on wildlife recreation in Vermont.

A 2000 public attitude survey of 1005 Vermonters determined that the protection of fish and wildlife resources, including habitats, as well as the opportunity to engage in wildlife-dependent recreation was important to 97 percent of respondents (Responsive Management 2000).

Congress Responds

In the early 1990’s state fish and wildlife agencies partnered with a variety of non-government organizations and businesses to advocate for broader federal funding to address the needs of species that were not hunted or fished and to “keep common species common.” However this was never implemented. The funding initiative was labeled Teaming with Wildlife. Initially, an excise tax on wildlife–related recreational equipment, such as binoculars and wildlife viewing guides, was identified as the best funding alternative. Over time, and with congressional encouragement, a different model was developed, one utilizing...
offshore gas and oil receipts. The concomitant legislation was termed the Conservation and Reinvestment Act (CARA).

Congress responded with a new annual appropriation in Fiscal Year 2001 first called the Wildlife Conservation and Restoration Program and later the State Wildlife Grants Program. Since that time, the Vermont Fish and Wildlife Department has been eligible for more than 3 million dollars of federal funds. These dollars have vastly improved our ability to fund new research, inventory, and management initiatives for species such as bobcats, timber rattlesnakes, lake sturgeon, butterflies, and the Bicknell’s thrush.

Wildlife Action Plan
The receipt of federal dollars has been predicated on individual state commitment to develop a plan. These documents must be submitted to the U. S. Fish and Wildlife Service for approval by October 1, 2005. Even though the Wildlife Action Plan is expected to address the full array of wildlife in a state or jurisdiction, the focus is on “species of greatest conservation need.” The federal legislation prescribes eight elements for consideration in the ACTION PLAN, as per below:

1) Identify wildlife distribution and abundance: Provide information on the distribution and abundance of species of wildlife, including low and declining populations as the State fish and wildlife agency deems appropriate, that are indicative of the diversity and health of the State’s wildlife.

2) Describe location and condition of key habitats: Describe the locations and relative condition of key habitats and community types essential to conservation of species identified in (1).

3) Describe key problems and research needs: Describe problems that may adversely affect species identified in (1) or their habitats, and priority research and survey efforts needed to identify factors which may assist in restoration and improved conservation of these species and habitats.

4) Describe and prioritize conservation actions: Describe conservation actions proposed to conserve the identified species and habitats and priorities for implementing such actions.

5) Monitor species, habitats and conservation actions: Describe plans to monitor species identified in (1) and their habitats; monitor the effectiveness of the conservation actions proposed in and, adapt these conservation actions to respond appropriately to new information or changing conditions.
6) Develop a plan review process: Describe procedures to review the Wildlife Action Plan at intervals not to exceed ten years.

7) Coordinate with other plans: Coordinate the development, implementation, review, and revision of the Action Plan with Federal, State, and local agencies and Indian tribes that manage significant land and water areas within the State or administer programs that significantly affect the conservation of identified species and habitats.

8) Include public participation: Describe public participation in the development, revision, and implementation of the Action Plan and projects and programs.

Plant conservation and education and law enforcement projects are not eligible for State Wildlife Grants funding. We expect that species, community and landscape level conservation will provide secondary benefits including addressing the needs of many plant Species of Greatest Conservation Need (SGCN). Furthermore, the Vermont Action Plan include some education and law enforcement-based conservation strategies under the assumption that the Action Plan will have planning and funding development beyond the requirements of the State Wildlife Grants program.

Though the secondary benefits to plants and other non-SGCN species noted above are expected to accrue from the implementation of the Action Plan, this Plan should not be viewed as a biological diversity (biodiversity) conservation plan. State Wildlife Grant funds will be targeted to conservation of SGCN. Just as historic and ongoing game management efforts benefit multiple non-target species of plants and wildlife, so to will the Wildlife Action Plan.
Expected Results and Benefits of the Wildlife Action Plan

The Action Plan should provide the following benefits:

- Provide a science-based foundation for understanding the issues involved in addressing wildlife needs.
- Reduce the risk of further Threatened and Endangered Species listings that would impose additional regulatory requirements on Vermont businesses and communities.
- Provide a common conservation vision to guide state and federal agencies as well as sportsmen’s and non-profit conservation organizations, in improving prospects for effective coordination and reducing conflicts.
- Put existing land and resource management and conservation needs into a broader context, providing recognition for the contributions that landowners and land managers are already making towards a long-term conservation strategy.
- Increase the effectiveness of limited conservation resources by identifying areas where conservation activities will provide the greatest benefit to cost ratio. Encourage conservation actions to be more proactive and less reactive and improve coordination between agencies and organizations to ensure cost-effective conservation.
- Allow use of existing programs to more effectively provide incentives or technical assistance to private landowners for voluntary actions to conserve natural resources on private lands.
- Identify the need for additional landowner incentive or technical assistance programs more easily.
- Demonstrate Vermont’s commitment and capacity to conserve species and habitats. Vermont's reputation for a high quality of life and preservation of natural resources—one of the state's core strengths in attracting businesses—will be maintained.
- Build a reliable, science-based data set to provide a “big picture” view (biophysical region and statewide) of Vermont's wildlife resources to establish current condition and measure changes into the future. These data will allow state agencies to work with the public and private sector to more effectively.
- Conserving Vermont’s wildlife will maintain and perhaps increase the numbers of Vermonters and visitors who interact with and recreate in the outdoors.
- Vermont’s eligibility for future conservation funds from State Wildlife Grants will be maintained. These funds can be used for conservation activities that benefit the environment, economy and communities of the state.
**Major Conservation Partners**

At the outset, it is important to acknowledge that the Vermont Wildlife Action Plan is *not* only, or simply, a Department plan. Instead, it is a blueprint for wildlife conservation *in Vermont*. The distinction is important and one that presupposes potential participation in achieving conservation strategies by a wide variety of management, education, and research entities.

Vermont has an outstanding history of citizen participation in the management of its fish and wildlife resources. This should come as no surprise given the high level of interest Vermonters have in wildlife, as noted above.

Even though sportsmen and women were at the forefront of early funding and conservation initiatives, and remain committed unto those ends, the past thirty years or so has seen the emergence of other interests including birders and nature photographers, land and habitat conservation advocates, and hikers and paddlers, to name a few. The Vermont Wildlife Action Plan has benefited from the strong, helpful, and encouraging planning assistance of many individuals and organizations (table 1-1).
The development of Vermont’s Wildlife Action Plan has been a collaboration of dozens of agencies, organizations and businesses representing diverse interests who have joined forces to better conserve wildlife. As of August 1, 2005 the following entities have signed on as Conservation Partners

| American Chestnut Foundation                  | US Fish & Wildlife Service, Lake Champlain Fish & Wildlife Resources Complex |
| Association of Vermont Conservation Commissions | US Fish & Wildlife Service, Missisquoi NWR                           |
| Audubon Vermont                               | US Fish & Wildlife Service, Nulhegan Basin Division                   |
| Burlington Electric Department                | University of Vermont Rubenstei School of Environment and Natural Resources |
| Center for Woodlands Education                 | University of Vermont Botany Department                               |
| Connecticut River Watershed Council           | Vermont Agency of Transportation                                     |
| The Conservation Fund                         | Vermont Association of Snow Travelers                                  |
| Consulting Foresters Association of Vermont   | Vermont ATV Sportman's Association, Inc                              |
| Ducks Unlimited                               | Vermont Cooperative Fish & Wildlife Research Unit                     |
| Echo                                         | Vermont Coverts                                                       |
| Endangered Species Committee                  | Vermont Department of Environmental Conservation                        |
| Fairbanks Museum & Planetarium                | Vermont Department of Forests, Parks & Recreation                     |
| Forest Watch                                  | Vermont Department of Housing & Community Affairs                    |
| Green Mountain National Forest                | Vermont Farm Bureau                                                   |
| Hunters, Anglers & Trappers Assoc of Vermont  | Vermont Federation of Sportsmen's Clubs                              |
| International Association of Fish & Wildlife Agencies | Vermont Fish & Wildlife Board                                    |
| Keeping Track, Inc                            | Vermont Forest Products Association                                  |
| Lake Champlain Basin Program                  | Vermont Institute of Natural Sciences                                |
| Lake Champlain Committee                      | Vermont Land Trust                                                   |
| Lake Champlain International, Inc.           | Vermont League of Cities and Towns                                    |
| Lake Champlain Land Trust                     | Vermont Loggers Association                                           |
| Lake Champlain Walleye Association            | Vermont Natural Resources Council                                     |
| Lewis Creek Association                       | Vermont Outdoor Guides Association                                   |
| Marsh-Billings-Rockefeller NHP               | Vermont Regional Planning Commissions                                |
| National Wild Turkey Federation               | Vermont Ski Area Association                                          |
| National Wildlife Federation                  | Vermont State Grange                                                 |
| Natural Resources Conservation Service        | Vermont Trappers Association                                         |
| The Nature Conservancy                        | Vermont Woodlands Association                                        |
| New Haven River Anglers Association           | Wildlands Project                                                    |
| North Country Environmental & Forestry        | Wings Environmental                                                  |
| Northern Forest Alliance                      | Representative Steve Adams                                           |
| NorthWoods Stewardship Center                 | Office of Congressman Sanders                                         |
| Ruffed Grouse Society                         | Office of Senator Jeffords                                            |
| Ryegate Power Station                         | Office of Senator Leahy                                               |
| Sierra Club                                   |                                                                         |
| Society of American Foresters                 |                                                                         |
| Smugglers Notch Resort                        |                                                                         |
| Sportsmen Inc                                 |                                                                         |
| Trout Unlimited                               |                                                                         |

Table 1-1: Wildlife Action Plan Conservation Partners
Statewide Themes for Action

In the course of reading or evaluating this Action Plan, it becomes apparent that there is a great deal of commonality, or unifying themes, between taxonomic groupings of species of greatest conservation need. For example, habitat conservation, improved knowledge of distribution and abundance, and education are obviously foundational, given their redundancy. Concomitantly, it is possible to make some strategy groupings that would appear to be pivotal in achieving conservation success. Before doing so, it would be helpful to make four observations.

First, in 2002, the International Association of Fish and Wildlife Agencies (IAFWA) adopted a position paper entitled “The Value of the North American Model of Fish and Wildlife Conservation” (Prukop and Regan 2005). The Vermont Fish and Wildlife Department is a member of IAFWA and has incorporated the Model into its strategic planning. Several recommendations for, or to, state agencies are instructive for thinking about wildlife conservation in the context of the Action Plan, including the need to maintain wildlife as a public trust (i.e., not owned by anyone), the need to use science to make management decisions, and the importance of regulating trade and possession of wildlife.

Second, conserving Vermont’s Species of Greatest Conservation Need requires that we address problems at the appropriate scale. Recommended strategies address problems at the species level (e.g., the illegal harvest of wood turtles through education and law enforcement), the habitat level (e.g., the lack of early successional habitat through forestry), the landscape level (e.g., maintaining and restoring connectivity of riparian areas) and the regional/national and international levels (e.g., habitat loss along migration routes).

Third, collaborative efforts to address habitat concerns related to development, including assessment of direct and indirect impacts, avoidance and minimization of impacts and appropriate mitigation early in a project's planning processes can not only protect habitat from alteration, degradation, conversion and fragmentation, but can speed the project more successfully through the permit review process.

Fourth, Vermont wildlife has already benefited from a strong environmental ethic, deeply rooted connections to the land, based on traditional forestry and agricultural economies, and a very high percentage of Vermonsters who engage in recreational activities that are dependent on wildlife. In other words, there are compelling and inherent reasons for optimism about the future of wildlife conservation in the Green Mountain State.
All that being said, there are state, regional, national, and international factors that are a cause for concern regarding habitat viability, clean water and air, international trade in wildlife, and a diminution of understanding about wildlife and its management, in part because of complex social factors. Each of the four sets of presuppositions above forms the backdrop for the conservation strategies presented below and throughout this document.

### Habitat Themes

1) Through education, legislation, and policy improvements address issues such as sprawl, poorly planned development, and global warming that drive habitat conversion, degradation and fragmentation (The Wildlife Society¹). Possible tools include:

- Maintain and expand incentives for private landowners such as the Wildlife Habitat Incentives Program (WHIP), Landowner Incentive Program (LIP), and the Current Use Program (officially the Agricultural and Managed Forests Land Use Value Program) and other appropriate management agreements. Consider amending tax policies and providing tax abatement and/or other tax relief to reduce the pressures on property owners to subdivide and sell property (parcelization). Create incentives for rural landowners to enhance their land as working forests or farms. Strengthen the Current Use program to include management of land for the benefit of wildlife as a conforming use. Increase funding for the Vermont Housing and Conservation Trust fund.

- Continue to utilize permitting processes such as Act 250 to address critical habitat considerations where appropriate.

- Promote and enhance programs designed to manage retention of open space including forestland and agricultural land. Assist local and regional land-use planning organizations such as towns and regional planning commissions. Support plans that identify natural resources and wildlife values and take steps to conserve habitat such as the designation of growth centers that focus development in existing centralized communities. Consider restoring existing village or urban facilities and infrastructure. Increase funding for Rural Community Assistance programs.

- Acquire critical habitats in fee title or easement. Follow Vermont Agency of Natural Resources land acquisition policies and procedures (VANR 1999) for parcels and rights therein that will be owned by the State.

---

¹ The Wildlife Society, the North America Section of the Society of Conservation Biology and the U.S. Society for Ecological Economics have all taken similar positions on the need to address the negative impacts of economic growth on wildlife. The American Fisheries Society and the Ecological Society of America are currently considering similar positions.
2) Through education, incentives, legislation, and policy efforts address global warming and pollutants such as mercury and acid deposition.

- Support the recommendations of the Climate Change Action Plan developed by the Conference of New England Governors and Eastern Canadian Premiers (2001) and local and regional initiatives such as the Alliance for Climate Action to reverse the growth of greenhouse gas emissions in Vermont.

- Work with state and federal agencies and legislators to ensure adequacy of and compliance with interstate emissions standards for greenhouse gases, mercury, and sulfur dioxide and nitrogen oxides that cause acid deposition.

3) Develop a collaborative, statewide and regional wildlife monitoring and adaptive management program to develop SGCN baselines, measure progress toward desired outcomes for SGCN, and to evaluate and improve the effectiveness of the conservation strategies proposed here and throughout this document. Such a program will:

- Identify key protocols and systems for data collection and sharing.
- Identify goals and objectives for SGCN conservation.
- Determine SGCN distribution and abundance, identify indicators and trends, and assess habitats, natural communities and other appropriate land classification categories to provide data at scales relevant to a variety of users in order to more effectively conserve SGCN.
- Identify conservation opportunity areas where the likelihood of successful conservation is strongest and the conservation needs of wildlife and their habitats would be best met.

**Population Level Themes**

4) Through policy and education support the enforcement of existing laws that protect species of greatest conservation need. For example:

- Prevent the importation or movement of invasive, non-native species.
- Regulate the illegal taking, trade, sale and collection of species of greatest conservation need.

**Technical Assistance & Outreach Themes**

5) Work to develop and implement landowner incentives, technical assistance and education for sustainable management of species of greatest conservation need, including:

- Develop and enhance partnerships between local, state and federal agencies, non-governmental organizations, industry and private individuals to increase the focus on species of greatest conservation need and conservation of associated habitats.
• Provide outreach materials and technical assistance to encourage sound land management and compatible recreation practices (e.g., VFWD’s habitat planning manual *Conserving Vermont's Natural Heritage*). Demonstrate management goals and practices on public lands, especially Wildlife Management Areas.

• Proactively collaborate with transportation planners and engineers regarding the location and design of new and expanded roadways.

• Look for opportunities to implement Action Plan strategies through existing federal cost-share programs (e.g., USDA’s Conservation Reserve Enhancement Program, the USFS Forest Legacy Program and the USFWS Landowners Incentive Program).

• Disseminate ecologically sound information through appropriate media, e.g., develop a website with information on all species of greatest conservation need in Vermont. Include information on identification, natural history, conservation, management suggestions, reporting, and contacts.

• Promote increased cooperation and communication among all agencies and groups concerned with conservation education and resource management.

• Showcase the success of the Action Plan through regular outreach to partners.

• Develop outreach and education programs that promote the conservation of SGCN and the habitats that they depend on, and increase awareness of the importance of maintaining or restoring these species.

**Regional Coordination Themes**

6) Provide regional coordination for conservation and management of species of greatest conservation need.

• Look for opportunities for collaborative management between jurisdictions (e.g., Lake Champlain, Atlantic Coast Joint Venture, the Connecticut River Joint Commission, the Conte National Wildlife Refuge, and the Northern Forest Lands Council).

2. Vermont Overview

*Vermont Cares about Wildlife Conservation*

It is no mystery why people enjoy living in and visiting Vermont. This state has what so many other once rural places have lost: a wealth of wildlife and scenic beauty, traditional working landscapes that support viable local economies, and desirable social and cultural attributes – low crime rate, helpful neighbors, and close-knit villages and towns.

Wildlife, scenic beauty, and the landscape that supports this way of life are not only vital parts of Vermont's rural character and identity, but are highly valued by Vermont residents. Based on 2001 public opinion survey results from the U.S. Fish and Wildlife Service, Vermont ranked first in the nation in percentage of residents that actively observed wildlife (60%). The results also show that hunting, fishing, and wildlife viewing expenditures in Vermont totaled $386 million, an increase of $6.42 million over the previous survey in 1997. At least 280,000 Vermont residents participate in wildlife-associated activities. This constitutes nearly 50% of the state’s resident population – the highest percentage in the nation. In addition, approximately 307,000 non-residents participate in wildlife-associated activities in the state each year. These statistics represent a significant contribution to the state’s economy and underscore the strong connection Vermont residents and non-residents have to the land and wildlife.

Vermont’s diverse natural resources, which include forests, clean waters, vibrant fisheries, healthy wildlife populations, rare species, significant natural communities, and a working landscape, provide people with the opportunity to, among other things, hunt, fish, trap, watch wildlife, hike and work the land.

*The Vermont Landscape—an Overview*

Vermont’s landscape is a rich tapestry of mountains, valleys, woods and wetlands, with a fascinating geological history. It is Vermont’s natural landscape that enriches the lives of those who live here and draws so many visitors to the state. It is this same landscape that
provides us with clean air, clean water, and habitat for thousands of species of plants and animals.

Understanding Vermont’s natural heritage requires understanding the physical landscape. The configuration of mountains, valleys, wetlands, lakes, and rivers is crucial in determining the distribution of natural communities, habitats, and native species.

The following broad environmental factors influence the distribution of species, habitats and natural communities: climate, bedrock geology, surficial geology, topography, hydrology, and land use history. These factors that comprise and influence the Vermont landscape and subsequently the flora and fauna of the state are explained below.

**Climate**

Vermont’s lowest land point is the shore of Lake Champlain, only 95 feet above sea level. Vermont’s highest point is the Chin on Mount Mansfield, which rises to 4,393 feet. The distance between Lake Champlain and the summit of Mount Mansfield is only 20 miles, but in that short distance, the climate, topography, and vegetation change considerably. On the shores of Lake Champlain, where the growing season is 150 days, shagbark hickories and sweet gum trees grow. Apple orchards are common in this environment as well as dairy farming due to the influence of climate on growing season. On the summit of Mount Mansfield, where the growing season is limited to 90 days, red spruce and balsam fir grows in stunted and contorted mats, bending to the direction of incessant winds.

Climate is major factor in determining the distribution of natural communities, habitats, plants and animals. Elevation provides a means for understanding the influence of climate on wildlife and habitats in Vermont because climate changes in relatively short distances with change in elevation. Thus the affect of climate on biota can easily be observed.

**Geology**

Vermont’s bedrock composition is varied and thus, influences important factors such as soils, hydrology, and subsequently plant
distribution and abundance. These variations influence in part the
distribution of wildlife. The rocks that comprise the Southern Green
Mountains were formed more than 570 million years ago. The rocks
of the Champlain Valley and the Northern Green Mountains date
from a time 540 to 443 million years ago when Vermont was the edge
of a warm, tropical sea. The remains of marine mammals that
inhabited that sea can be found in the Champlain Valley’s limestone
rock. The youngest rocks in Vermont are the granites, like the stone
that makes up the Barre granite quarries. These rocks were formed
200 to 400 million years ago as a result of deep underground magma
welling up and hardening.

Whether the bedrock is limestone or granite – or some other kind of
rock – is particularly important in the distribution of natural communities
and plants because each kind of rock has its own unique physical and
chemical composition. For instance, rich fens, a rare type of wetland with
plants that require high levels of calcium, occur almost exclusively in
areas where limestone or similar calcium-rich rock are found.

Vermont’s surficial geology is defined by the sands, gravels, clays, peats,
and other deposits found on top of the bedrock as a result of both
glacial activity and post-glacial events (like flooding) that continue
today. Bedrock and surficial geology together have a profound
influence on the soils in which Vermont’s plants grow.

**Topography**

Topography describes the physical landscape and influences the
distribution of plants, animals, and natural communities. The soil on
the top of a mountain tends to be shallow and dry, whereas the soil at
the base of a slope tends to be deep, moist, and rich in organic matter
because of the downslope movement of plant litter and soil. Cliffs,
for example, offer a unique habitat for specialized groups of plants,
and may offer important denning habitat for bobcat and nesting sites
for peregrine falcon. Certainly, topography influences the quality and
distribution of winter habitat for white-tailed deer in Vermont.
Hydrology
Water and its movement have a profound influence on animals, plants and natural communities, and ecosystem processes. Lakes, ponds, rivers, and streams provide habitat for a diversity of fish, aquatic plants, aquatic invertebrates, and other organisms. Wetlands form in waterlogged soils, either in low-lands where water collects by gravity, in uplands where impermeable soils create perched water tables, or at the highest elevations where fog and abundant rain provide a constant supply of water for wetland plants and animals.

Land Use History
Land use history has influenced the distribution of plants and animals across Vermont. For instance, the degree and type of forest cover have a great influence on the species that occur in an area. Vermont has more forest today (78%) than it had in the mid-1800s (25%), and the effect of this change on wildlife has been dramatic. Additionally, Vermont’s agricultural activity also affected the soils and the plants that grow in them.

Biophysical Regions of Vermont
The five factors described previously combine to create eight distinct biophysical regions. It is important to consider Vermont’s biophysical regions when assessing and planning for the conservation of wildlife (Fig 2-1). For example, what may be a common species in one biophysical region may be rare in another, thus, increasing the importance of conserving habitat for that species in the region in which it is rare. Vermont’s biophysical regions are described below.

Northeast Highlands: Granite bedrock dominates this cool region, which is characterized by large wetlands, remote mountains, and lakes and ponds. Spruce and fir dominate the lowlands as well as the high elevations, whereas northern hardwoods cloak the mid-elevations.
Forty-three percent of this region is conserved, the highest percentage of any of Vermont's biophysical regions.

**Northern Vermont Piedmont:** Calcium-rich soils combine with a cool climate to support mixed forests and Northern White Cedar Swamps, Fend and other interesting natural communities in this region. The uplands have fine agricultural soils, but a short growing season. Eight percent of the region is conserved.

**Southern Vermont Piedmont:** Calcium-rich soils and rolling hills make this a good place for agriculture. The climate is average for Vermont, except in the extreme southeast where it is quite warm. Northern hardwoods and red oak dominate the vegetation. Seven percent of the region is conserved.

**Southern Green Mountains:** A broad plateau is dotted with a few dominant peaks and several ski areas. Climate is cold and rainfall is relatively high. Northern hardwoods, spruce, and fir dominate, and there are a number of small lakes and ponds. Thirty-three percent of this region is conserved.

**Northern Green Mountains:** This area has a cool climate and high elevations and is mostly forested. Northern hardwoods dominate the side slopes, whereas high elevations have spruce and fir as well as Alpine meadow habitat. Twenty-six percent of the region is conserved.

**Champlain Valley:** This region of Vermont has a warm climate and abundant fertile farmland. The Champlain Valley contains both northern hardwood forest and also various species of oaks and hickory. It has some of the state's most significant natural diversity and also the state's most densely populated areas. Nine percent of the region is conserved.

**Taconic Mountains:** The slate belt of Vermont and New York is found in this region. The Taconics are dramatic wooded hills dominated by sugar maple, beech, and yellow birch forests. Dry oak and hickory forests are found on the lower elevation knolls, while
spruce and fir occur at the highest elevations. Ten percent of the region is conserved.

**Vermont Valley**: The Marble Valley has marble and limestone with glacial deposits on the valley walls, abundant springs, and wetlands. About 10 percent of the region is conserved.

**Vermont’s Landscape—an Historical Perspective**

Vermont’s landscape has long been altered by people. Native cultures grew crops, harvested animals for food and clothing and lived in established settlements. During the 17th and 18th centuries, land was cleared for the development of agricultural economies. By the mid-1800s, 75% of Vermont’s forests were cleared for agriculture, and in particular, sheep farming. These changes had an effect on the state’s waters, forests, and wildlife. Even some species of wildlife such as beaver and deer that had been common, nearly disappeared from the land. As other influences caused people to begin to move towards the western United States, lands were abandoned and forests began to regenerate.

With the return of the forest and the work of the Vermont Fish & Wildlife Department and partners the recolonization and reintroduction of animal species, beaver, deer, wild turkey, fisher, and others that had declined have now returned and are today abundant. These species and more stand as great testament to Vermont’s commitment to wildlife conservation and the resiliency of the forests and wildlife. Many species of fauna and flora, however, have not recovered. The passenger pigeon, for instance, is now extinct, and some large predators such as wolves and mountain lions that once roamed the New England forests, are no longer present.

**Vermont’s Contemporary Land Use**

Agriculture and forestry still support Vermont’s economy in significant ways. These elements of Vermont’s business and economic communities offer great opportunities for wildlife conservation because they allow private landowners to realize a
financial return from their land while keeping the land in an undeveloped or natural condition. Many of these land-based business interests are excellent stewards of the land and wildlife.

Vermont non-industrial forestland owners have a long history of active engagement in the management of forest resources throughout the state. Since the advent of the Vermont Use Value Appraisal Program (a.k.a. Current Use Program) 11,000 landowners have brought almost 1.5 million acres of forestland under forest management. Many of Vermont forestland owners manage their lands for wildlife and forest resources and seek to enhance their management skill through their involvement in non-profit organizations advocating sustainable forest management such as Vermont Coverts: Woodlands for Wildlife, Inc., Vermont Woodlands Association, and the Woodland Owners Association. These stewards provide strong examples of Vermonters taking steps to conserve our wildlife resources.

The landscape of Vermont is also supporting increasing demand for residential and commercial development. The Vermont Forum on Sprawl reports that the rate of development in Vermont is 2.5 times greater than the rate of population growth. Like other New England states, residential development is often dispersed in rural and suburban areas rather than in existing village and urban communities.

Based on data from the U.S. Census Bureau, the population of Vermont in 2004 is 621,394 and has increased by 2.1% since 2000. The human population of Vermont is quite small compared to many other states.

Parcelization is a term that describes the subdivision of land into smaller and smaller pieces and multiple ownerships. This phenomenon has been shown to have an impact on the ability of local forest product economies to remain sustainable. Parcelization is occurring in parts of Vermont where larger tracts of land are
subdivided into smaller multiple smaller parcels for residential development. This may have some influence on Vermont’s forest products interests in the future and at the very least is something that should be considered with respect to maintaining viable forest products economies for all the positive benefits that they provide to the state and its wildlife.

**Contemporary Problems Impacting Wildlife in Vermont**

An extraordinary amount of work went into developing this report. Our technical teams assessed the status all of Vermont's birds (268), fish (94), mammals (61), reptiles and amphibians (42) and many group of invertebrates ranging from mussels, to beetles, to butterflies and isopods. From there Species of Greatest Conservation Need (SGCN) were selected and the technical teams then described the habitat these species used, problems impacting the species and their habitats, and strategies to conserve both species and habitats. Add to this assessments and recommendation for 25 major landscapes and community types and it's not surprising that this report tops the 1,000-page mark.

The interesting thing is this: if you take two steps back from the details to view the big picture, the view is not a grim one. Yes there are more than 300 SGCN but the picture we see is a hopeful one, a roadmap to healthy wildlife populations for Vermont's future. The reasons are repetition, economies of scale, and cooperation.

The problems most frequently identified as impacting SGCN are, loss of habitat (due to conversion, degradation, fragmentation and lack of needed successional stages), the impacts of roads and trails, pollution and sedimentation, invasive species, climate change, and data gaps and information needs. Though these are big, serious and complicated problems they are much easier to address than hundreds of smaller problems.
Loss of Habitat: Due to Degradation, Conversion, Fragmentation or Lack of Needed Successional Stages

These four categories are not mutually exclusive and problems can often logically be placed into more than one category depending on the particular stress it causes for a species or habitat.

Habitat Conversion: The complete transformation or loss of a habitat by human action (examples include: filling a wetland to create a grassy field, converting a forest stand into a parking lot, or damming a stream to create a reservoir). Though many agencies and organizations work diligently to conserve important wildlife habitats, Vermont continues to lose approximately 525 acres of significant habitat each year to regulated development alone. According to the Vermont Environmental Board, regulated development in Vermont constitutes approximately one-third of the total development that occurs on an annual basis. Significant habitats are those habitats that are addressed by various statutes, largely Act 250, and include deer winter habitat, wetlands with significant wildlife functions, habitat for rare, threatened and endangered species and several types of habitat necessary for the survival of black bears. These habitats represent only a few of the many habitats that are affected by loss due to development.

Habitat Alteration/Degradation: A lessening of the quality of a habitat by human action stopping short of complete conversion (examples include: the reduction of mast (fruit and seed) production in a forest stand, riprapping a streambank, and significant land use changes adjacent to a habitat such as replacing a forest stand on the edge of a wetland with a housing development.

Habitat Fragmentation: The breaking up of habitats into smaller, non-contiguous patches as a result of habitat conversion (e.g., housing, commercial development, roads, utility lines). Fragmentation can: 1) render important habitats inaccessible (such as isolating a den site from a feeding site), 2) isolating
populations (for example grassland butterflies, spotted salamander, and tiger beetles); and, 3) degrade remaining habitat patches through edge effects that favor edge-tolerant species such as raccoons and crows, as well as invasive exotic species that can out-compete native and rare species. The result of habitat fragmentation is often increased predation, increased mortality, reduced mobility and changes in habitat micro-climates.

**Inadequate Distribution of Successional Stages:** The lack of either late, mid or early successional habitat in appropriate patch size and/or juxtaposition can be a problem for some SGCN especially as fragmentation makes it harder for species to move between forest patches (examples include ruffed grouse and woodcock which prefer early successional forest stands, American marten which prefers late-successional stands and Canada lynx which depends on a mix of forest stages).

**Impacts of Roads and Trails**
In the last quarter of the 20th century, Vermont expanded its road system by an average of 26 miles per year to a total of about 14,251 miles. The number of vehicle miles traveled by Vermont residents is growing at seven times the rate of population growth, according to information from the Vermont Agency of Transportation (1999). Transportation systems, including some hiking and recreation trails, can cause numerous problems for SGCN including: vehicle-wildlife collisions; reducing animal and fish passage, thus limiting habitat availability and isolating populations; vehicle emissions of pollutants such as ozone and greenhouse gases; and facilitating the spread of an exotic, invasive species into otherwise healthy areas.

**Pollution & Sedimentation**
The introduction of exotic materials from point and non-point sources can significantly impact SGCN, particularly aquatic species. Pollutants & sediments include sands and silts, chemicals and toxins; excess nutrients from farm and municipal sewage plants; garbage and other solid waste; radioactive materials; road salt; excessive noise; excessive heat; and light pollution that disturbs animals and disrupts migration patterns. Sediments can be a problem for SGCN through their physical
presence alone. For example, soils can wash into a stream from a construction site and smother fish eggs and other aquatic species living in the spaces between rocks and gravel streambed.

**Invasive Exotic Species**
The introduction and spread of nuisance exotic and native species (plants and animals) may lead to the elimination of native wildlife populations, threaten long-term stability of habitats and even lead to extirpation by out-competing a native species, displacing its food source or altering a key process or function of a habitat. Invasive exotic species in Vermont include Eurasian watermilfoil, purple loosestrife, common buckthorn, Japanese knotweed, Morrow’s honeysuckle, goutweed, black swallow-wort and zebra mussels. Additional information can be found in Appendix K.

**Climate Change**
Long-term changes linked to global warming and other climate issues can lead to major changes in habitat availability (e.g., high elevation habitats, wintering areas and migration stopovers) (Glick 2005), vegetative composition and location (e.g., the movement up in elevation or north in latitude, invasion by exotic pests), climate variability (e.g., change in snow depth, rainfall and/or natural disturbances). Many specific details as to how climate change is affecting Vermont's wildlife today is a major unknown, but the pervasiveness and scale of the problem requires that we begin planning to address it now.

**Data Gaps and Information Needs**
A lack of information has been identified as a principal impediment to the conservation of many Species of Greatest Conservation Need. In particular we need additional information on the distribution and abundance of SGCN and the status of local and statewide populations, a better understanding of habitat needs, life-history information, and information related to SGCN movement and migration. This information will help to fine-tune strategies and guide management for SGCN.
**The Silver Lining**

We noted at the beginning of this section that recurring problems actually give us hope that we can conserve Vermont’s Species of Greatest Conservation Need because if we address a problem for one species we're likely to do the same for many others. Similarly, several conservation strategies outlined in this report including habitat restoration, encouraging wildlife-compatible resource use, providing education and technical assistance to landowner and managers and providing economic incentives for conservation come up again and again in this report. The good news here is that we can focus our limited conservation resources on the strategies that will provide the biggest bang for the buck.

Therefore to the list of major issues impacting Species of Greatest Conservation Need we'll add one problem that our technical teams did not identify directly in their assessments but that was often discussed during team meetings—the lack of sufficient funding for wildlife conservation. Without sufficient funding we will not be able to implement many of the conservation strategies identified in this report. The State Wildlife Grants program is a critical first step in funding SGCN conservation, but more is needed. And, to make the most of SWG funds, Vermont will have to develop the required matching stateside funds.
Conservation Success!
Keeping Common Species Common

In spite of the changes to the Vermont landscape, the fact is, Vermont remains a relatively rural state with an abundance of conserved land, private landowners who are excellent stewards of the environment, and many wildlife conservation success stories. The public opinion survey results (U.S. Fish & Wildlife Service 2001) speak volumes for the bright future of wildlife conservation in Vermont—that is, the public has a strong interest in and dedication for the conservation of Vermont’s natural heritage.

Moreover a review of past and ongoing wildlife conservation efforts provides proof of our collective ability to recover and conserve wildlife and the habitats required for their survival. It also identifies the key building blocks for successful conservation.

In 1724, when the first European settlement was established at Fort Dummer, near Brattleboro, the state was primarily forested and had abundant fish and wildlife populations including passenger pigeons, fisher, wolves, deer, black bear, beaver, and salmon. However, by 1865 many of these species would be present in far fewer numbers or on the cusp of extirpation because of unregulated harvests, habitat loss and habitat degradation.

Hunting and fishing license fees, soon after the turn of the 20th century, coupled with federal wildlife and sportfish restoration act dollars, enacted in the 1930’s and 1950’s respectively, established a financial framework in support of conservation. These monetary resources enabled Vermont, and the other states, to conduct inventories and research, acquire habitats, and provide conservation education to the public. Today, some of the species of low abundance 150 years ago are now once again common throughout the State. Consider, for example:

**White-tailed deer:** Numbers were so low in the late 1800’s that no open season was offered and deer were transplanted from New York. Through extensive research, harvest management, and habitat
protection, Vermont can now support in excess of 150,000 deer with 48 days of hunting opportunity, annually.

**Wild turkey:** This bird was extirpated from the state in the 1800’s. Birds were reintroduced to the state in 1969. We now have more than 40,000 turkey and both fall and spring hunting opportunities.

**Fisher:** This mid-sized carnivore was extirpated from the state. Animals were reintroduced to Vermont beginning in 1959, and this predator now thrives on the Vermont landscape.

**Anadromous fish on the Connecticut River:** Migratory fish in the Connecticut River, including Atlantic salmon, American shad, striped bass and river herring were reduced or eliminated in 1798 by a dam built in Turners Falls, Massachusetts. With the construction of fish passage at dams, and active restoration programs shad, stripers and herring are now abundant in the lower river, and annual runs of Atlantic salmon have been restored to the lower river after a nearly two hundred year absence.

**Trout and salmon in Lake Champlain:** Landlocked Atlantic salmon disappeared from Lake Champlain in the 1850’s, and native lake trout were gone by 1929. A restoration program was begun in the 1970’s in cooperation with the State of New York and the US Fish and Wildlife Service, and these fish are plentiful once again in Lake Champlain where they support a popular fishery that brings hundreds of millions of dollars into the regional economy each year.

**Lake sturgeon:** A combination of dam construction, pollution and over-fishing reduced lake sturgeon populations in Lake Champlain in the early 1900’s to the point that the commercial fishery was abandoned and all fishing for sturgeon was prohibited in 1967. Since this fishing closure sturgeon conservation has benefited from water quality improvements, better water flows at the dams, and outreach to anglers to release any sturgeon they catch. Recent studies have documented successful natural reproduction of sturgeon in all four of their historic spawning rivers in Vermont.
Peregrine falcon, osprey, and common loon: These birds were gone or nearly gone from the state by the mid-1900's. Through focused management (e.g., the construction of artificial nesting platforms, water level management, and public education), each of these three species has recovered sufficiently that they've recently been removed from the state's endangered species list—a first for any species in Vermont.

These success stories suggest that new dollars will produce new success stories for the future. In other words, the fish and wildlife profession has demonstrated the will and the competence to restore and manage wildlife. The Wildlife Action Plan, coupled with sustained funding and the dedicated participation of partners, will offer a template for advancing the success stories to a new suite of species.
The Importance of Education, Law Enforcement and Wildlife-Associated Recreation to Wildlife Conservation

Through the State Wildlife Grants program (SWG) Congress provides every state with critically needed funds for wildlife conservation. Congress' intention is to support proactive and strategic efforts to prevent future Endangered Species Act listings—in other words, to keep common species common. To meet Congressional intent, states are compelled to employ all of their best conservation tools including education, wildlife-associated recreation and the creation and enforcement of wildlife protection laws and regulations. These are among the most proactive, strategic and time-tested tools in any conservation tool box.

The details of the SWG program legislation, however, currently preclude states from using SWG funds for law enforcement and recreation projects. A limited amount of SWG funds can be used for conservation education, but only in a supporting role in the implementation of a conservation strategy (e.g., signage explaining the purpose of a restoration project). This poses a dilemma for states trying to implement a truly comprehensive wildlife action plan because it restricts their use of three vital conservation tools. Moreover, it limits the participation of three significant conservation constituencies from participating in Wildlife Action Plan implementation—the law enforcement, education and outdoor recreation communities.

A limited number of education and law enforcement conservation strategies specific to particular species or habitat categories were addressed in the species and habitat conservation summaries of this report (Appendices A and B). We recognize that alternative funding sources are needed for their implementation. In this section of the Wildlife Action Plan report we present additional conservation strategies based on conservation education, wildlife-associated recreation and law enforcement. It is our hope that future renderings of the State Wildlife Grants program, along with other funding mechanisms will provide for the implementation of these strategies and other others in their realms.

Conservation Education

Wildlife and human communities depend on healthy ecosystems and ecological processes. Their functions are essential for our quality of life and for the Vermont economy. Conservation strategies that follow a sound education model can foster healthy public behavior and attitudes toward land and wildlife conservation. Furthermore, strong educational programs that expand Vermonters’ ecological literacy will enhance the credibility and effectiveness of other conservation efforts and build support for future efforts. Finally, the public plays a key role in influencing legislators, who in turn affect policy and funding decisions. Recommended strategies include:

- Foster and enhance educational partnerships to maximize efficiency (e.g., develop volunteers, outreach to teachers and youth group leaders to deliver programs)
- Ensure that sound messages, curricula, and best educational practices are followed to maximize our efforts (e.g., provide teacher training, curriculum support materials for teachers and students,
Define a land stewardship message that promotes the conservation and ethical use of Vermont’s fish, wildlife, and plants, and the habitats that sustain them.
Focus outreach and education efforts to enable the public to make informed decisions on issues affecting ecosystems in Vermont such as: habitat degradation and fragmentation, threats to fish and wildlife species and their habitats, the value of working rural landscapes and other rural lands, the sustainable and ethical utilization of wildlife.

The connection between education to wildlife conservation is recognized nationwide. The International Association of Fish and Wildlife Agencies (IAFWA) is sponsoring the development of a national strategic plan for conservation education, the resulting plan will make conservation education a top priority for state fish and wildlife agencies (Case 2005).

Wildlife-Associated Recreation
Hunting, fishing, trapping, and wildlife viewing have a long heritage in Vermont and Vermont leads the nation in wildlife viewing (US DOI 2001). By providing the means for more people to connect with wildlife, we can foster more and stronger relationships to the natural world. Applying the concept of stewardship through recreation Vermonters can become knowledgeable about and appreciate wildlife, natural communities, and conservation in ways that promote citizen interest in contributing to conservation. Recommended strategies include:

- Work with the broader community of recreation groups (e.g., outdoor guides, birders, sportsmen and women, hikers, paddlers, climbers, spelunkers, mountain bikers and snowmobile and ATV associations) to foster partnerships that build a stronger wildlife ethic among members.
- Expand educational programs on watchable wildlife, including such topics as birding, wildlife photography, animal track identification, and backyard habitat. Target population centers, with a focus on youths and families.
- Increase information available to the public on how and where to watch wildlife. Provide information to encourage watchable wildlife practices, such as viewing, photographing, and feeding, in a manner that is ethical, safe, and consistent with protecting the welfare wildlife resources.
- Foster a recreational ethic based on the concept of giving back to the natural world.
- Include an educational component in recreation activities making the connection between our actions and the impact on wildlife.
- Involve Vermonters in activities that will increase their understanding of wildlife and land stewardship and the influences of human activities on wildlife, in order to build public support for fish and wildlife conservation (e.g., citizen science projects such as the bird atlas, butterfly survey and other wildlife inventories, teacher training courses, streambank plantings, and field classrooms).
- Encourage responsible outdoor recreation through programs such as "Stop Aquatic Hitchhikers," "Leave No Trace," "Stay on the Trails," and "Be Bear Aware."
Recent projects
A joint VFWD-Vermont Federation of Sportsmen's Club project in 2003 is a good example of a wildlife-based recreation project. Using funds from the short-lived Wildlife Conservation and Restoration Program (WCRP), a predecessor to the State Wildlife Grants program, public access to the Blueberry Hill Wildlife Management Area was enhanced.

The Fish & Wildlife Department recently developed and helped implement a combined physical education/conservation curriculum for Vermont schools.

Statewide Comprehensive Outdoor Recreation Plan (SCORP): In addition to the Wildlife Action Plan, states are developing comprehensive plans for outdoor recreation as a requirement for receiving support from the Land and Water Conservation Fund (LWCF). The National Parks Service in the U.S. Department of the Interior administers the LWCF. The National Parks Service’s term for this planning process is known as the SCORP, which stands for Statewide Comprehensive Outdoor Recreation Plan. The Department of Forests, Parks & Recreation (FPR) is leading the development of Vermont's SCORP. The document will be ready in 2005.

Law Enforcement
The creation and enforcement of fish and wildlife laws are among our society's oldest attempts to conserve wildlife. Vermont's first game wardens were appointed in 1779 to protect deer and were called “Deer Reeves.” Law enforcement is an effective conservation tool and has been at the core of wildlife conservation ever since.

State game wardens prevent the illegal taking, trade, sale, collection and importation of wildlife by proactive enforcement of fish and wildlife laws. Game wardens also prevent and investigate the unlawful destruction of critical habitat, trespass and disturbance of refuge areas and sensitive breeding grounds and enforce the regulations and permits that govern wildlife research, education and rehabilitation.

Law enforcement professionals strive to be proactive: Game wardens are an integral part of the Fish & Wildlife Department's outreach and education programs. Wardens teach conservation at schools, civic organizations and conservation camps and are often the first, and sometimes, only contact that the general public has with a conservation professional. Recommended strategies include:

- Maintain staffing of game wardens and compliance officials statewide sufficient to ensure the adherence of all laws pertaining to fish, wildlife and habitat conservation. State game wardens conduct routine patrols providing enforcement of boat, ATV and off road recreational vehicles to address the illegal operation and destruction of sensitive habitat and wildlife areas.
- Review, update, and enforce regulations controlling the importation and possession of exotic and potentially harmful fish and wildlife species and their pathogens.
Recent projects
As people interact more and more with wildlife, the number of wildlife-human conflicts increases. In 2002 Vermont game wardens responded to more than 1,000 calls from the public on issues such as rabies and damage to property. If not adequately addressed members of the public might try to resolve the issues themselves in a manner unduly detrimental to wildlife. Many encounters require a physical response by a warden to prevent human injuries or disease exposure. Funds from the short-lived Wildlife Conservation and Restoration Program (WCRP), a predecessor to the State Wildlife Grants program, helped enhance VFWD's wildlife-human conflict management efforts through additional equipment, outreach materials and staff training. These enhancements improved responsiveness and effectiveness in addressing these real and growing needs.

All for one and one for all: Law enforcement, Education & Recreation
It should be clear to a reader by this point that not only is each of these three tools critical to the long-term conservation of wildlife, but that they are all tightly intertwined. For example, our best opportunities to instill the message of conservation in the public are when they are out in nature recreating. And, state game wardens are often the ones to deliver the message. Furthermore, outdoor guides and other recreationalists often provide tips to wardens and compliance officers regarding habitat degradation or the illegal taking of wildlife, and by doing so they send a strong message to the general public that Vermonter care about wildlife.
Vermont Department of Forests, Parks & Recreation: Current Efforts Related Wildlife Conservation

The mission of the Department of Forests, Parks & Recreation is to practice and encourage high quality stewardship of Vermont’s environment by:

- monitoring and maintaining the health, integrity, and diversity of important species, natural communities, and ecological processes;
- managing forests for sustainable use;
- providing and promoting opportunities for compatible outdoor recreation; and
- furnishing related information, education, and service.

To fulfill our mission, the Department will continue to work, as we have for almost a century, for sound management and sustainable use of Vermont’s forests, forest land, other natural resources, and outdoor recreation opportunities.

The Vermont Department of Forests, Parks and Recreation pleased to have had the opportunity to be involved in Vermont’s first Wildlife Action Plan. As the proposed conservation strategies are implemented, this plan could have a significant impact on the management of public and private forest lands within the state.

Without healthy, sustainable forests in Vermont, attempts to conserve wildlife would be in vain. The animals and the habitat are inextricably linked… Forests should continue to dominate our state’s landscape to ensure healthy wildlife populations.

The vast majority of Vermont’s forests are privately owned and unless landowners can expect a reasonable return from their forest resources, maintaining land as part of a working landscape may be difficult. Equitable taxation (through programs like the Use Value Appraisal Program) and strong local markets for forest products are critical to ensure the conservation of forested habitats by this largest portion of landowners. The Department’s efforts (in this respect) can be broadly categorized into program management, state lands management, information and education, forest protection and economic development.

With respect to programs which most directly effect wildlife resources, our activities include:

State Land Management: Manage in a sustainable manner state-owned land for the purpose for which it was acquired and the wishes of the public, and in cooperation with the Fish & Wildlife Department and Department of Environmental Conservation. This amounts to 348,000 acres (1999). Primary goals include protecting land and water, maintaining ecosystem integrity, maintaining or enhancing biodiversity, protecting historic and cultural sites, providing compatible recreation opportunities, and producing wood products. In accordance with long-range management plans we additionally, construct and maintain high-quality forest roads for management activities, developed parks and recreational sites, and controlled recreational access for public uses. The Department also manages and/or monitors conservation easements on over 42,000 acres (1999) of private land. Both state-owned land and easements include those purchased with assistance from the Vermont Housing and Conservation Trust Fund, federal Land and Water Conservation Fund, the Forest Legacy Program, and State Trails Fund to ensure they are maintained for the public values for which they were acquired.
The Forest Legacy Program (FLP) is a federal grant program to protect forestlands from conversion to non-forest uses. The Vermont Department of Forests, Parks & Recreation is State Lead Agency for Vermont's Forest Legacy Program. The program is entirely voluntary. Landowners who wish to participate may either sell the property as fee simple title (all rights), or only a portion of the property rights and retain ownership of the land. The use of conservation easements allows the land to remain in private ownership and ensures that important public values such as wildlife habitat, natural areas, forest resources, and outdoor recreation opportunities are protected.

**Use Value Appraisal (Current Use Program):** Administration of the forestry portion of the use value appraisal (current use) tax program on the million + acres (1999) of actively managed, private forest land enrolled. This includes providing public information, approving management plans, and inspecting parcels to insure compliance with standards and the management plan.

**Private Land Management -- Technical Assistance:** Provide information and technical assistance to private landowners on how to manage their land properly. This includes helping landowners understand and evaluate the timber, wildlife, ecological, historical, and aesthetic values of their woodlands. Advising landowners on the availability of private consulting services to help them carry out their management objectives.

**Acceptable Management Practices (AMPs):** Provide information and materials, and monitor practices that maintain water quality -- minimizing erosion, sedimentation, and temperature changes -- on logging jobs. Assist loggers and landowners to implement AMPs. Respond to citizen complaints. Assist in fact-finding and prosecution of violations. Provide education directly and through partnerships.

**Acquisition of Land/Interests in Land:** Continue to provide adequate state land for conservation, outdoor recreation, timber production, and other purposes consistent with a statewide policy and plan (the Agency’s Lands Conservation Plan, effective July 1999). This includes exchanges, fee-simple acquisitions, acquisitions of interests in land, and identification/disposal of surplus lands.

Forest Land Conservation: Following up the recommendations of the Vermont Forest Resources Advisory Council (FRAC) and Northern Forest Lands Council (NFLC) continue to explore ways to:
- Enhance local rural-based economies through public policies that encourage, rather than discourage, investment in forest-dependent businesses.
- Conserve tracts of undeveloped forest land.
- Explore continually-evolving issues about Vermont's forest land.

**Natural Areas Designation/Protection:** Continue to identify, designate, and protect areas of significant biodiversity and/or geologic interest on state land. Presently 33 areas are designated.

**Forest Health Monitoring:** Assess, monitor, and report on the health of Vermont's forest resources by periodic measurements of tree condition and other ecosystem parameters (e.g., soil chemistry and structure, indicator plants and animals, vegetation structure), following national, regional, and state protocols. This includes Vermont Hardwood Health Survey, North American Maple Project, National Forest Health Monitoring Program, and Forest Inventory and Assessment (FIA).
**Forest Insect and Disease Management:** Protect Vermont's timber, sugarbush, urban forest, Christmas tree, and non-commercial forest resources from significant loss of ecological, economic, or aesthetic value due to damage by forest insects, disease pests, or other biotic and abiotic stressors. Assess role of natural insect and disease outbreaks in overall ecosystem integrity. The Department provides information, data, and technical assistance to landowners, managers, and state and federal agencies. We also implement procedures for handling insect and disease outbreaks and assist in research conducted by other organizations.

**Vermont Forest Ecosystem Monitoring (VForEM):** Participate as a major partner in VForEM to: Provide information needed to understand, protect, and manage forested ecosystems within a changing global environment. Promote understanding of the conditions, trends, and relationships in the physical, chemical, and biological components of forested ecosystems in Vermont. Promote efficient coordination of multi-disciplinary environmental monitoring and research among federal, state, and private entities.

**Conservation Education:** Continue and improve interpretive education programs and materials for individuals, schools, groups, and state park visitors, on natural resources, their management, and other related topics. This includes the summer park naturalist program; fall park naturalist program for Vermont students; Project Learning Tree coordination; production of needed written, audio, photographic, and video materials; providing information via the Internet; networking with other educational institutions, organizations, and programs on special projects; and filling requests for natural resources career information. Continue work on alignment of curriculum materials (PLT) with “Vermont Framework of Standards and Learning Opportunities.” Continue work with Vermont Institute for Science, Math, and Technology (VISMIT) and Department of Education on natural resources education. Provide information on state land.

**Informal and Formal Education:** Continue strong commitment throughout the Department, in all activities, on education in our informal contacts with the public, presentations, workshops and demonstrations in the field, school visits, activities on state lands, and other means. This includes continuing education and training for loggers, foresters, and others resource workers. Produce and provide printed materials and public use maps; fill requests for alternative formats. Work with the Department of Education on natural resources management education as a requirement in school curricula, including such topics as wildlife, forestry, water resources, recreation, etc.

**Research and Monitoring:** Participate in a variety of research and monitoring projects (often with cooperators, such as the University of Vermont and U.S. Forest Service) on important natural resources issues, such as forest health, recreational use of lakes, economic contributions of forest-based businesses, and forest practices. Make the data and information available and useful to the public and special interests.
The concept that healthy wildlife populations support healthier natural systems upon which we all depend goes to the heart of our mission at the Department of Environmental Conservation (DEC) As such, DEC as been pleased to participate in the development of the Wildlife Action Plan.

The DEC is one of three departments in the Agency of Natural Resources. The Department’s activities include: monitoring and ecological assessment, education, grants and regulatory oversight of the quality of air, surface water, drinking water, and groundwater, wetland and surface water ecosystems; and waste management and disposal. Department vision and mission statements describe 1) the future condition that the Department collectively wishes for Vermont and the balance that the Department seeks between Vermonters and the resources that the Department manages and 2) what the Department is working to accomplish respectively.

DEC Vision

“We envision a Vermont where people live in harmony with diverse and healthy natural systems; appreciate and enjoy our natural resources; understand the environment; work together responsibly to reduce waste and risks to human health and the environment; and prosper without significant degradation of natural systems. We envision a Vermont where people breathe clean air, drink clean water; eat safe food; and live in a sustained and healthy environment.”

DEC Mission

“To preserve, enhance, restore, and conserve Vermont’s natural resources, and protect human health, for the benefit of this and future generations.”

The Department’s work is organized into six programs: Air, Drinking Water, Surface Water, Waste, Groundwater and Earth Resources, and Management. Each of the Department’s programs has identified goals developed strategies for achieving those goals. Goals and strategies that address wildlife conservation include:

Air: Goals of the Air program include “to maintain a level of air quality in Vermont that supports a healthy, diverse ecosystem.” Strategies to achieve this goal include: maintaining base compliance, permitting, monitoring, and outreach and education programs; install air pollution control devices on regional air pollution generators having a discernable impact on Vermont; develop action plans for reducing chemicals which exceed Hazardous Ambient Air Quality standards.

Surface water: Goals of the Surface Water program include “to maintain and enhance a level of surface water quality, quantity and stream morphology that supports the integrity of healthy ecosystems.” Strategies to achieve this goal include: maintain basic compliance, permitting, planning, monitoring, outreach, and education activities; reduce phosphorus loading to Lake Champlain through point and non-point source controls and improve municipal policies and bylaws; develop, with extensive education and public participation, watershed management plans for all major and minor watersheds that will outline strategic actions to monitor, restore, maintain and enhance the quality of waters within
each basin; provide education and technical assistance to enable communities, local organizations, and individuals to understand and minimize their impact on the watershed environment; develop assistance programs to enhance the management of dams, including removal when appropriate; develop and maintain a morphologically based stream restoration approach to river management; restore river reaches and lakes that are altered by artificial flow and water level management.

**Groundwater and Earth Resources:** Goals of the Groundwater and Earth Resources Program include “to conserve Vermont’s earth resources.” Strategies to achieve this goal include: maintain basic compliance, permitting, planning, monitoring, mapping, outreach, and education activities; complete investigation and remediation of contaminated sites; produce maps of all known sources and locations of contaminated groundwater.

**Waste:** Goals of the Waste program include “to reduce hazardous and solid waste generation through pollution prevention, source reduction, reuse and recycling, to ensure safe management of solid and hazardous wastes that are generated, and to mitigate health and environmental impacts of improper waste disposal actions and accidental releases.” Strategies to achieve this goal include: maintain basic compliance, permitting, planning, monitoring, outreach, and education activities; provide waste prevention information, assistance and recognition; provide solid and hazardous waste facilities management and oversight; provide emergency spill response and management of contaminated sites.

The above provides a summary of Department of Environmental Conservation goals and strategies related to environmental conservation, many of which directly and indirectly benefit wildlife. Strategies include many long-established ongoing activities, including technical assistance, monitoring, grants, and regulatory services. Each program works in partnerships with citizen groups, municipalities, businesses and other government agencies including the Vermont Fish & Wildlife Dept and the US Fish & Wildlife Service. These coordinated efforts are critical to the success of making progress towards each of the program’s goals. A few of those activities are described below.

Biodiversity monitoring is an ongoing activity conducted by DEC biologists. Monitoring activities are conducted to evaluate the status of selected biological species and communities. Specific activities include: 1) distributional surveys of plant and animal species listed by the Vermont Endangered Species Committee as endangered, threatened, rare, or of special concern; and 2) monitoring of biological communities or community types whose diversity is threatened (e.g., Lake Champlain mussel and cobble/shale invertebrate communities threatened by zebra mussels). Data are used to: 1) describe species distributions; 2) identify species/communities at risk; and 3) develop management plans for the protection of identified species/communities (e.g., Lake Bomoseen bladderwort relocation).

DEC biologists, in collaboration with other state and federal agencies, have been involved in a variety of activities related to the ecology of wetlands. These activities include: investigations onto the occurrence and potential causes of malformations among Northern leopard frogs in Vermont; a study of the biological communities of vernal pools; demonstrations of the use of herbivorous insects for the control of invasive exotic plant species in lakes and wetlands.
The Department is increasingly using watersheds as the basis for water quality protection and management, and to determine assessment and monitoring priorities. Through the Department’s educational efforts, watersheds are now the focus as people learn about their individual role in causing and controlling pollution, protecting water resources, and in preserving the land. The Department, following the "Guidelines for Watershed Planning," is conducting seven Basin Planning Processes that includes working with local land owners and other residents to restore impaired waters and formulate strategies to restore and protect waters throughout the watersheds. As part of this effort, bioassessment and biomonitoring will increasingly guide water quality management.

For more information about DEC programs and projects go to:
http://www.anr.state.vt.us/dec/dec.htm
Why is the Vermont Agency of Transportation Concerned about Fisheries and Wildlife Issues?

The Vermont Agency of Transportation (VTrans) has a productive working relationship with the Vermont Fish and Wildlife Department, and numerous activities related to fisheries and wildlife described in the following pages. There are several important reasons for this work.

1. **Safety:** Wildlife on Vermont's highways represents a significant risk to humans. Numerous lives are lost and there are billions of dollars in property damage every year nationally due to vehicle-animal collisions.

2. **Fiscal Benefits:** There are potential fiscal benefits to the state and the agency by reducing wildlife collisions and better planning for wildlife and fisheries impacts from transportation including:
   - Reduced insurance claims.
   - Increased hunting and fishing license revenues from healthier and more numerous deer and moose herds and a healthy indigenous fishery.
   - Improved planning lessens the potential for regulatory battles and thus reduces transportation project costs.
   - Reduced bridge and culvert maintenance costs. Bridges and culverts that provide fish passage are subject to fewer impacts from sediment and debris transport and erosion.

3. **Stewardship:** Protection of wildlife and improved fisheries are important issues for Vermonters. Transportation has been shown to have negative effects to fisheries and wildlife including: increased animal mortality from vehicle collisions; direct and indirect effects to habitat from the existing transportation system, increased traffic, and proposed improvements including new and expanded roadways; reducing animal and fish passage, thus limiting habitat availability and isolating populations; and the effects of pollutants from vehicles such as ozone and green house gases on the state's ecological health. VTrans needs to be a good environmental steward and respond to the public's concerns about fish and wildlife protection.

   Stewardship means better working relationships with regulatory agencies—improved trust, communication, coordination and collaboration - which all help to avoid confrontation in the regulatory process.

4. **Wise Allocation of Resources:** Hundreds of state bridges and culverts are insufficient regarding fish passage. Federal and state dollars to repair, retrofit, and replace these structures are severely limited. Planning and cooperation with the Vermont Department of Fish and Wildlife is needed to make investments that will have the most benefit to all indigenous aquatic organisms.
5. **Prudence in the Regulatory Process:**

- Working with Fish and Wildlife biologists to better plan, predict problems, and evaluate resources in advance of project design prevents conflicts regarding specific species and habitats during regulatory processes.

- Planning for mitigation at the watershed or bioregion level, rather than mitigating transportation impacts on a case by case basis has the potential to reduce mitigation costs and have greater wildlife benefits.

- Transportation agency knowledge and involvement in wildlife and fisheries planning means that indirect and cumulative impacts (under the National Environmental Policy Act NEPA) are better coordinated and more easily addressed for large projects.

**The National Perspective**

**Road ecology** - the notion of accommodating wildlife and fisheries movement around and through the transportation system and minimizing habitat fragmentation - is being considered nationally through the Federal Highway Administration (FHWA) and at increasing numbers of state DOTs.

States are employing a mix of underpasses, bridge extensions, culvert installations and modifications and associated fencing and ecowalls to facilitate and guide wildlife movement. Research is also underway through the auspices of the National Cooperative Highway Research Program to investigate how to identify the best wildlife crossing alternative for a site, design guidance and standards, maintenance costs, and a tool to determine cost effectiveness.

Several states, including Vermont, a leader in the Northeast, have also been conducting research and setting policy regarding practice and design guidance for culvert installation, design and prioritization for fish passage.

Transportation planners and highway engineers, biologists, state and federal environmental regulators, and environmental interest groups have been sharing information and research for several years within the context of the biannual International Conference on Ecology and Transportation (ICOET). This first gathering of experts supported in part by the FHWA occurred in 2003 at Lake Placid, New York. The theme for the 2005 conference, which will be held later this year, is "On the Road to Stewardship." The conference website (www.icoet.net/ICOET2005.html) explains that:

The 2005 "Stewardship" theme is designed to encourage conference presenters and participants to share information about projects and best practices that show how they are moving beyond regulatory requirements in order to respond to broader scientific and community-driven concerns related to the consideration of ecological concerns in transportation planning, project development, construction, operations and maintenance.

**History in Vermont and Initiatives Underway**

For the past several years, the Vermont Agency of Transportation has had several important initiatives related to road ecology. This work is a collaborative partnership with the Vermont
Fish and Wildlife Department and includes a Wildlife Crossing Steering Committee, chaired by VTrans’ Director of Program Development. Initiatives include:

- The effects of new transportation projects on habitat and consideration of animal and fisheries passage are considered early in the project planning process. These effects are also considered in the maintenance and upgrading of the existing transportation infrastructure. One recent and very successful example of the former is agreement reached among the regulatory agencies regarding a major expansion of Route 78 through the Missisquoi National Wildlife refuge.

- The first-ever northeast regional wildlife and transportation conference held in 2004, a follow-up to the 2003 ICOET conference, and designed to forge a regional strategy regarding transportation and wildlife issues.

- VTrans and other partners on the Aquatic Organisms Steering Committee including the Vermont Fish & Wildlife and US Forest Service assessed the condition of over 200 large culverts (greater than 6’ in diameter) in the Upper White River Watershed. The survey revealed that about one half of the existing large culverts under the state and interstate systems never pass fish. The remaining culverts only pass fish some of the time, and all of the structures suffered from structural damage and nearby stream degradation. Additional survey work in the Connecticut River Watershed during 2005 will help set future Agency culvert retrofit and replacement policy and priorities.

- A statewide GIS habitat database for use as a predictive model for making transportation decisions related to habitat connectivity. The database utilizes data collected by VTrans Operations and Maintenance road crews as well as data from the Vermont Fish and Wildlife Department.

- An inter-agency agreement that will create habitat for the eastern racer, a snake thought to have been extirpated from the state for at least 25 years that was recently discovered on VTrans property.

- Researchers from the University of Massachusetts Amherst have been retained to conduct a ground-breaking study on the efficacy of wildlife crossing structures being installed on the Bennington Bypass.

- VTrans and VDFW staff continue to monitor existing Interstate structures to identify potential crossing structures that are already part of the transportation system.

- Finally, VTrans staff continue their involvement in a habitat training program (recognized by AASHTO in 2003 with a National Environmental Stewardship Award nomination) that gets diverse personnel in to the field with wildlife experts from Keeping Track, Inc, the Vermont Herp Atlas, VFWD and others to learn how their work as transportation professionals can reduce impacts and reconnect habitat.
The Future
The Vermont Agency of Transportation's environmental policy adopted in 2004 recognizes the need for the agency to be proactive regarding its environmental stewardship responsibilities. The effects of the transportation system on Vermont's fisheries and wildlife are noted above. VTrans' approach in the past has included research, dialogue and partnerships with the Department of Fish and Wildlife and other interests. This work will continue in 2005 including:

- Norwich University students performing both pre-construction and post-construction aquatic studies during the summer of 2005—upstream, downstream, and within large culverts on the Agency's critical list.

- A culvert design workshop planned for July 11-15, 2005 for ANR and VTrans personnel with the goal of developing a set of design criteria that address hydraulics, debris and sediment transport, and the passage of all indigenous aquatic organisms.

Developing Vermont's Wildlife Action Plan

Process and Organization

Timeline

The creation of Vermont's Wildlife Action Plan began in August 2003 when a Steering Committee of Vermont Fish & Wildlife Department directors and program leaders began regular scoping meetings. A project coordinator was hired in January 2004 and January to May 2004 was devoted to: reviewing federal guidelines, planning literature and past planning efforts; designing the Action Plan organizational structure and development process; and soliciting the support of stakeholder organizations and agencies. The identification of Species of Greatest Conservation Need (SGCN) occurred from May through September 2004. Habitat delineation for SGCN, problem assessment and strategy development occurred from September 2004 through January 2005. Integration and conservation planning ran from October 2004 through April 2005. Review and additional input by the Department, agencies and other stakeholders and the general public, ran from February through July of 2005. Final document preparation and editing occurred from May through August 2005. The anticipated submission date of the Action Plan is September 1, 2005.

The Action Plan Steering Committee identified five primary concepts during the scoping process that should frame the development of the Wildlife Action Plan:

1. Conserve, enhance and restore Vermont’s wildlife and wildlife habitat.
2. Represent good science and conservation planning.
3. Identify conservation priorities yet remain flexible and open to new opportunities.
4. Be a strategy for the entire state; one that all agencies, organizations and individuals can find useful.
5. Build and support advocates for wildlife conservation.

The Action Plan Steering Committee recognized that meeting these goals required the resources, participation and ingenuity of many conservation-minded individuals, organizations and agencies. This in turn required a development process that included stakeholders and conservation partners to the greatest extent possible.

Organizational Structure

Six technical teams (Species Teams), two coordination teams (Integration Team and Steering Committee) and two advisory committees (Conservation Strategy Review Team and Conservation Partners) were created to develop the Wildlife Action Plan (Fig 3-1). Team descriptions follow below. Full charters for each team can be found in Appendix D.

Steering Committee: (Fish and Wildlife Department directors and program heads and the Action Plan Coordinator). The Action Plan Steering Committee is the executive body for Action Plan development and implementation with statutory responsibility for completion.
of the Action Plan and management of State Wildlife Grant funds. The Steering Committee provides leadership and organizational commitment to ensure success of the Action Plan; encourages meaningful participation and buy-in among partners; and, appoints members to technical teams. See Table 3-1 for a list of Steering Committee members.

Wildlife Action Plan Coordinator: Manages the Action Plan project, supports activities of the technical and coordination teams, directs outreach and communications efforts, and writes website, newsletter and Action Plan content.

Figure 3-1: VT Wildlife Action Plan Teams and Committees

Conservation Partners: (representatives of state & federal agencies, non-profit organizations, large landowners, utilities, State legislators, academics, and others).
Conservation Partners provide guidance and recommendations to the Action Plan Steering Committee; review SGCN lists and Action Plan drafts; nominate experts for participation on Species, Integration and Conservation Strategy Review teams; and, help implement the Action Plan upon its completion. The Conservation Partners committee is open to any and all organizations that wished to participate. See table 1-1 for a list of conservation partners.

Species Teams: (selected Fish and Wildlife staff, conservation partners, and other wildlife conservation experts). There are six Species Teams: Bird, Fish, Invertebrate, Mammal, Plant, Reptile & Amphibian (Herps). These teams develop and refine lists of species of greatest conservation need; assess species distribution and abundance, identify habitats, communities, problems & strategies; develop monitoring and performance measures; recommend draft strategies for managing species of greatest conservation need; address comments made by Conservation Partners during interim review. See Table 3-1 for a list of Species Team members.

Integration Team: (Species Team leaders plus additional Fish & Wildlife staff and non-staff experts in wildlife conservation). The Integration Team develops criteria for designating species of greatest conservation need; keeps Species Teams on schedule; organizes species into groups based on habitat needs, synthesizes reports of the Species Teams and strategies developed by the Conservation Strategy Review team; identifies gaps in information and addresses special habitat and natural community needs; and prioritizes strategies and solutions to conservation challenges. See Table 3-1 for a list of Integration Team members.

Conservation Strategy Review Team: (State and federal agencies and non-profit organizations). The Conservation Strategy Review team (CSR) includes a main team as well as an Education CSR and a Law Enforcement CSR. The CSR was added to the array of Action Plan teams and committees in direct response to early feedback from Conservation Partners. Partners wanted additional opportunities to participate in Action Plan strategy development. CSR members were selected by the Steering Committee from a pool of nominees submitted by Conservation Partners. See Table 3-1 for a list of CSR members.

The Conservation Strategy Review team reviews problems and draft strategies developed by the Species Teams and the Integration Team. The CSR can also develop additional strategies as needed. These teams will also help present the draft Action Plan to Conservation Partners and the general public during review sessions. Because staffing and budget limitations made it impossible to include conservation education and law enforcement professionals on every Action Plan team and committee the Education and Law Enforcement CSRs were created to insert key perspectives and ideas into the process in a strategic and cost-effective manner. Conservation Strategy Review team members will also help implement the Action Plan upon its completion.

### Outreach and Public Involvement

The Vermont Fish & Wildlife Department recognized that to fully meet our goals for the Action Plan we needed the resources, participation and ingenuity of many conservation-minded individuals, organizations. To honor the efforts of the people and organizations participating in this project the following guidelines developed by the International
Association of Public Participation (IAP2 2004) were utilized in planning and implementing the public involvement process for Vermont's Action Plan:

1. Public participation includes the promise that the public's contribution will influence the Wildlife Action Plan.
2. The public participation process involves participants in defining how they participate.
3. The public participation process provides participants with the information they need to participate in a meaningful way.
4. The public participation process communicates to participants how their input affected the development of the Wildlife Action Plan.

In addition to the involvement of Conservation Partner organizations and agencies noted earlier, additional outreach and public involvement efforts focused on the following groups:

**General Public**: The general public has been kept informed about the State Wildlife Grants and Wildlife Action Plan several ways. These include: ongoing publications of two Department newsletters (*Fish & Wildlife Conservation News* and *Natural Heritage Harmonies*), a website dedicated to Vermont’s Action Plan (http://www.vtfishandwildlife.com/SWG_home.cfm); presentations to conservation and wildlife oriented organizations, lectures at the University of Vermont; postings to listerves such as Vermont's science teacher listserve, and the general news and recreation media. Our public outreach goals were to inform the public that: wildlife may be at risk without our help and without adequate funds to conserve them; that with the financial support of State Wildlife Grants program, the Vermont Fish and Wildlife Department and Conservation Partners are developing strategies to conserve Vermont’s wildlife; and; the general public can view a draft Action Plan and provide comments in spring 2005.

**Endangered Species Committee**: The Endangered Species Committee (ESC) is a standing citizens committee of the Agency of Natural Resources. It advises the Agency Secretary on issues concerning the State's listed and potential endangered and threatened species. The committee reviews the endangered and threatened species list and makes recommendations to the Secretary about amendments and ways to protect listed species. The ESC is supported by taxa-specific Scientific Advisory Groups (SAGs). Positions on the ESC and SAGs are filled by experts from local, state and regional organizations, agencies and education/research facilities. The Endangered Species Committee was briefed on the Action Plan early in the process. Several ESC and SAG committee members serve as Species Team members.

**Fish and Wildlife Board**: The Fish and Wildlife Board is a citizens committee of the Fish & Wildlife Department responsible for reviewing and approving fish and wildlife regulations in the state. The 14 members each represent one Vermont county and serves for six years. The board has been kept informed of the progress of the Action Plan via VFWD newsletters and email. Two Fish and Wildlife Department Board members were invited to the introductory Action Plan meeting and who have received regular Action Plan updates via the Conservation Partner listserve. Robert Borowske, Board Chairman was also made a member of the Conservation Strategy Review team.
Internal Constituencies: Staff of the Wildlife and Fisheries divisions and the Nongame and Natural Heritage Program of the Vermont Fish & Wildlife Dept received periodic updates and briefings on Action Plan status through division meetings, postings to the Action Plan website and through email. Leaders and members of the Integration Team, the Conservation Strategy Review team and six Species Teams included staff in all seven VFWD offices in the state. Staff was encouraged to provide input on all aspects of the process.

Coordination with Other Agencies & Native American Tribes

Congressional guidelines require that each state Action Plan "coordinate the development, implementation, review and revision of the Action Plan with federal, state and local agencies and Indian tribes that manage significant land and water areas within the state or administer programs that significantly affect the conservation of identified species and habitats."

Native American Tribes: There are no Native American tribes within the borders of Vermont that are officially recognized by the state or by the federal Bureau of Indian Affairs. Further, there are no tribal entities that manage significant land and water areas within the state or administer programs that significantly affect the conservation of Species of Greatest Conservation Need or their habitats. Therefore, in developing Vermont's Action Plan no special efforts were made to reach out to the Native American community however all Vermonters including Native Americans were encouraged to take part in the development of the Action Plan as Conservation Partners and the general public input process.

Development: State and federal agencies concerned with wildlife and land conservation and management have been highly involved in the development of Vermont's Action Plan. All are considered Conservation Partners in the development of the Action Plan. Representatives of eight state and federal agencies serve on Action Plan technical and coordinating teams (Table 3-1) of the dozen agencies serving as Conservation Partners. Several agencies provided data used in the development of the Action Plan. These agencies, as well as inter-agency groups such as the Lake Champlain Ecosystem Team, have also been kept informed of the ongoing developments in the Action Plan through email and US mail and partner meetings. Presentations and briefings were made to the commissioners of sister agencies at the State Agency of Natural Resources—the Department of Forests, Parks and Recreation, and the Department of Environmental Conservation, the Agency Secretary, the Vermont Agency of Agriculture, the inter-agency Lake Champlain Ecosystem Team, Windsor County Regional Planning Commission, and representatives of the Vermont Department of Housing & Community Development, and the US Department of Environmental Protection.

The International Association of Fish & Wildlife Agencies (IAFWA) and the Region 5 US Fish & Wildlife Service (USFWS) played significant and indispensable roles as facilitators of interstate, regional and national coordination through 1) Electronic listserves-IAFWA nationally and USFWS regionally; and, 2) Meetings of States, Federal Agencies and Partners—IAFWA nationally (two meetings) and USFWS regionally (three meetings).

Implementation, Review & Revision: All Conservation partners, including federal, state and local agencies will be encouraged to take part in the implementation, review and revision
of the Action Plan. Plans for these steps can be found in chapter 5 Vermont’s Action Plan: Implementation and Review.

**Outreach Events and Products**

**Partner Meetings:** In March 2004 representatives of approximately 80 organizations and agencies interested in wildlife conservation and management were invited to an introductory Action Plan meeting. At this meeting the proposed Action Plan development process was presented. Through a series of discussions and brainstorming sessions the attendees helped the VFWD fine tune the process and focus on key issues. Participants were invited to take part in the development of Vermont’s Action Plan by participating as Conservation Partners, by nominating people to serve on Species Teams and the Integration Team, and by keeping their memberships informed and engaged in the Action Plan.

In June 2005 Conservation Partners met for a second time to discuss the draft Action Plan report and Action Plan implementation. All questions, comments and suggestions were recorded and a responsiveness summary was developed and shared with all partners shortly after the meeting. The Conservation Partner comment period for the Action Plan originally ran from June 20 to July 18, 2005 but was extended to August 12, 2005 for a total of more than seven weeks.

In July 2005 a two-week public comment period and two public meetings on the final draft Action Plan were held. This comment period was three weeks to August 12, 2005 for a total comment period of five weeks. Public meetings were advertised through the Department's website, in the Department newsletter, through the news media and with the help of Conservation Partners who encouraged their memberships to attend the meetings and to provide comments on the report. Comments on the Action Plan were accepted during the meetings, via email, US mail, telephone and the Action Plan website.

The Action Plan was a significant topic of discussion among partner and potential partners during a September 2004 regional conference on Wildlife and Transportation held in Vermont.

**Individual Partner Meetings:** More than 40 meetings with individual partner organizations and agencies were held during the development of the Action Plan. The purpose of the meetings included keeping interested partners informed and outreach to potential partners.

**Partner Correspondence:** Between May 2004 and July 2005 Conservation Partners received periodic updates tracking progress in the development of the Action Plan via email and US mail. This includes the distribution of responsiveness summaries to Partner feedback, the announcement of a website dedicated to the VT Action Plan; the release of a draft list of Species of Greatest Conservation Need, the responsiveness summary to the CSR team recommendations and planning for a review meeting on the draft Action Plan report. Partners were invited to comment on any and all aspects of the Action Plan process and report in all communications. See Appendix E for a sample of correspondence and partner updates.
Species Team, Integration Team and Conservation Strategy Review team meetings:
The six Species Teams and Integration Team began meeting in May 2004 with most having
monthly meetings at least through January 2005. The Conservation Strategy Review team met
in Dec 2004 and February and March of 2005. These meeting were open to Conservation
Partners and the general public. Meeting schedules were posted to the Action Plan website.

Media: The Action Plan Coordinator managed the project's media campaign. Press
advisories were released three times during the life of the project. Stories and editorials ran in
two of the state's major newspapers and an unknown number of local and regional papers.
The project was also covered at least twice on television and on public and commercial radio
stations. Sample coverage is included in Appendix F.

Newsletters/Website: Fish & Wildlife Conservation News was created by the Fish & Wildlife
Department specifically to inform the public about the State Wildlife Grant program and the
projects it supports. Three issues were produced during the course of Action Plan
development. Natural Heritage Harmonies produced by the Nongame and Natural Heritage
program provided the public with information about Department projects, including work
on Species of Greatest Conservation Need. See Appendix G for sample newsletters. During
implementation of the Action Plan these newsletters will continue to inform and involve the
public in SWG and Action Plan conservation efforts.

In July 2004 the Department unveiled a website dedicated to Vermont’s Wildlife Action Plan
(http://www.vtfishandwildlife.com/SWG_home.cfm). This site contains background on
SWG, Action Plan requirements and background materials, links to Conservation Partners,
SGCN lists, team and committee meeting schedules, updates and Partner correspondence,
copies of press releases as well as copies of media coverage and answers to frequently asked
questions. Drafts of the Action Plan were also posted to the site and an online feedback and
comment form allowed people to submit comments electronically. During implementation
of the Action Plan the website will continue to inform and involve the public in SWG and
Action Plan conservation efforts.
Species & Habitat Conservation

Identifying Species of Greatest Conservation Need

Congress created the State Wildlife Grants program (SWG) in 2001 with the goal of preventing wildlife populations from declining to the point of requiring Endangered Species Act protections. To receive SWG funds, State Fish and Wildlife Departments agreed to develop statewide Wildlife Action Plans. Congress directed that the Action Plan identify and be focused on the "species of greatest conservation need."

Congress left it up to each state to identify their Species of Greatest Conservation Need (SGCN). The State Wildlife Grants program defines wildlife as "any species of wild, free-ranging fauna including aquatic species and invertebrates as well as native fauna in captive breeding programs intended for reintroduction within its previously occupied range." Furthermore, it was Congress' intent that SWG assist wildlife that have not previously benefited from other federal wildlife conservation and management programs (e.g., Federal Aid to Wildlife Restoration Act, Federal Aid in Sport Fish Restoration Act, or the Endangered Species Act). In Vermont, SGCN include:

- Species with declining populations;
- Species threatened or potentially threatened; and,
- Species that are so little known in the state that experts cannot yet ascertain status.

Though plants are not eligible for State Wildlife Grants Program funding, Vermont’s Action Plan does include plant SGCN. It is expected that habitat conservation efforts for wildlife SGCN will benefit at least some of the plants. Plant specific conservation strategies, if and when they are implemented, will be funded through mechanisms other than SWG. Several game and sportfish species are identified here as SGCN. We expect to target other established funding programs for the conservation of these species before tapping SWG.

Vermont began its process of identifying Species of Greatest Conservation Need (SGCN) with a systematic review of all its known wildlife. The review was designed to assist the teams selecting the SGCN by equalizing the between well-known wildlife species supported by large datasets and poorly understood species.

The Integration Team was tasked with developing review criteria (Table 3-2). Six Species Teams (Bird, Fish, Herptile (Reptile & Amphibian) Invertebrate, Mammal and Plant) conducted the reviews and selected SGCN with guidance and coordination provided by the Integration Team.

The Species Teams were provided with lists of species found in Vermont within their respective taxa (the Invertebrate team received the most up-to-date invertebrate list available but it is widely accepted that a complete list of the estimated 15,000-36,000 invertebrates in Vermont may never be possible (ANR 1995). The lists and supporting information were developed by the VFWD's Nongame and Natural Heritage Program (NNHP) using their Biotics© database and augmented with other databases, records and information from
Species teams met multiple times between May and September 2004 to conduct review. Data was captured in the Action Plan database.

Once the reviews were complete (Appendix A for SGCN, Appendix H for secure species) the Species Team selected SGCN using selection criteria (Table 3.3) developed by the Integration Team. Species were assigned conservation priorities of high, medium or low. Species ranked medium and high constitute Vermont's Species of Greatest Conservation Need. Low priority species were considered secure. There were a few cases where a specific Species Team approached their tasks differently:

**Bird Team:** An unusually rich collection of data and prior conservation planning efforts are available to bird conservators—far more than is available for other taxa. The Bird Team took advantage of this information by first focusing on species found on the watch lists of the North American Bird Conservation Initiative and Partners In Flight for Bird Conservation Regions 13 and 14 (Rosenberg 2004) as well as BBS route. Once watch list species were reviewed the team turned its attention to other species.

**Invertebrate Team:** It is estimated that Vermont is home to between 15,000 and 36,000 invertebrate species (VANR 1995). The vast majority are un-cataloged, un-studied and just plain unknown. Application of the review criteria to invertebrates on a species by species basis would be unproductive. Instead the Invertebrate team interviewed additional experts within Vermont, regionally and nationally to help in the identification of species and species groups of greatest conservation need.

**Plant Team:** The Plant Team also had to contend with a huge list of species—more than 2000 vascular plants (Flora 1993) and 600 bryophytes (Allard 2004). The team took advantage of plant conservation assessments previously conducted by the Agency of Natural Resources' Endangered Species Committee to create its list of Species of Greatest Conservation Need. All species ranked S1 (critically imperiled) and S2 (imperiled) became SGCN. Those SGCN also on the New England Plant Conservation Program list of regionally rare plants were then ranked High Priority. All others were ranked medium priority.

<td>Species may be vulnerable to some mortality and/or problems (e.g., habitat degradation) but population is abundant enough to tolerate negative forces</td>
</tr>
</tbody>
</table>
There is some variability between Species Teams regarding thresholds used for selection as SGCN (e.g. the herpitile team was the most conservative in selecting SGCN and the mammal team selected the most SGCN based on the need to address data gaps). This being Vermont’s first Action Plan our priority was not to ensure parity in numbers across taxa but rather to ensure that experts within each taxon were in accord regarding the species selected.

The list of Species of Greatest Conservation Need includes 144 vertebrate species (out of a total of 468), 192 invertebrate species or groups (out of an estimated 15,000-36,000) and 577 plant species out of approximately 2600 vascular and non-vascular species. See Table 3-4 for summary statistics on Vermont's SGCN.

This list was then reviewed by the Integration Team, Steering Committee and the Commissioner of the Fish & Wildlife Department. It was then made available to Vermont Fish & Wildlife staff, Action Plan Conservation Partners, the Action Plan Conservation Strategy Review team and the general public for feedback and comments via the Action Plan website.

Conservation of Species of Greatest Conservation Need

Fine Filter-Species

Once Species of Greatest Conservation Need were identified, technical teams set about developing individual species reports for each SGCN. Reports identified species distribution, habitat needs, problems affecting species and their habitats, research and monitoring needs and conservation strategies for each SGCN (Congressionally required elements #1-#5). Invertebrate SGCN were addressed in groups rather than as individual species. Fourteen invertebrate groups were created based on taxonomy (e.g., butterflies, crustaceans, tiger beetles) and habitat use (e.g., freshwater, grasslands, hardwood forests). Reports were not developed for plant SGCN. All data was entered into the Action Plan database.

Distribution for all SGCN was identified by biophysical region (Girton & Capen 1997) using terminology consistent with the Nongame Natural Heritage Program’s element occurrence tracking procedures. Distribution of fish SGCN and some additional aquatic SGCN was also
identified by 8-digit watershed unit (NRCS 2003). Historic occurrence was noted in a narrative for some of the rarer and extirpated SGCN.

Protocols for describing habitat were developed by the Integration Team in consultation with Species Teams. Habitat descriptions for SGCN include a narrative, elevation preferences, migrant status, home range and patch size requirements and landscape requirements (e.g., corridor needs, habitat mosaics or wetland complexes, preference for managed or passively managed forest, large grasslands or developed landscapes).

Research needs for each SGCN, where needed to determine species status or to identify problems, were developed by each Species Team. Research needs were assigned “high,” “medium” and “low” priorities.

Priority problems and potential risks to Species of Greatest Conservation Need were enumerated for each species. These were not exhaustive lists of all possible problems. Teams identified only those factors posing significant and potentially significant problems for a species. A narrative description was entered into the database. Species teams also assigned each problem to one of 22 habitat related and non-habitat related problem categories (Appendix C). These categories are the same as those used in Species of Concern Status Reports during the U.S. Forest Service's Forest Plan Revision process for the Green Mountain National Forest.

Species specific conservation strategies were also developed by the Species Teams. Strategies were designed to address the problems identified for each SGCN. Strategies were assigned either a "medium" or "high" priority status (low priority strategies are not included in the Action Plan) and each strategy was also assigned to a category (Salafsky 2004) to aid in organizing and review of strategies (Appendix C).

Strategies were not prioritized beyond this step. As a conservation guide for the state, Vermont's Action Plan is meant to provide guidance to organizations, agencies and individuals wishing to conserve wildlife. The varied goals and missions of the partners involved in the Action Plan span a broad spectrum of wildlife interests, skills and reach (some are local, others are state, regional and federal entities). No prioritization was found to satisfy all partners, however, the conservation need is deemed so great that there is room for everyone to select the species and habitats they find most important and implement the strategies they are most capable of working on. Detailed discussions with the Conservation Strategy Review team focused prioritization efforts on problems impacting SGCN and habitats (see below).

Coarse Filter - Conservation at Multiple Scales

To aid in the development of community and landscape level conservation strategies, all SGCN were assigned to at least one of more than 100 communities, cultural habitats and or landscapes. These elements were organized in four major groups: 1) forest and riparian/fluvial landscapes; 2) terrestrial natural communities and successional stage forests; 3) fish assemblages and lacustrine waters (lakes and ponds); and, 4) cultural habitats (see the tables 4-1 and 4-2 in the SGCN Conservation at multiple Scales section of Chapter 4). "Wetland, Woodland, Wildland - A guide to the natural communities of Vermont" (2000) by Thompson and Sorenson was used as the basis for terrestrial natural communities. Forest cover types (Eyre 1980) and U.S Forest Service Forest Inventory & Analysis types (USDA 2003) were used for early successional and managed forests. "A Classification of the Aquatic
Communities of Vermont" by Langdon et. al. (1998) was used as the basis for aquatic habitat designations and Reschke (1990) was adapted for cultural habitats.

These 100 categories were grouped into 24 major categories (see the tables 4-1 and 4-2 in the SGCN Conservation at multiple Scales section of Chapter 4) and the Integration Team developed assessments for each. Assessments included descriptions and general locations; current conditions; desired conditions based on the needs of SGCN associated with each category; a ranked list of significant problems impacting that category; conservation strategies to address each problem along with the identification of potential conservation partners and funding sources for each; and a listing of other relevant plans and planning processes.

The ranking of habitat problems was done according to a process described in Salafsky et. al. (2003) using four criteria: severity, scope, timing and reversibility (Table 3-5). This same process was employed by many other states developing Comprehensive Wildlife Conservation Strategies. Problems described in the habitat and community summaries (and in species summaries) are not comprehensive. Only those problems ranked as medium and high are included in this report. The decision to list only medium and high problems was a strategic one to focus attention on those problems determined or perceived to be most important. If additional problem(s) are later identified as significantly impacting a species or habitat it will be incorporated into the Action Plan database during project review and reporting. Strategies and actions to address additional problem(s) will also be eligible for SWG funding.

<td></td>
</tr>
</tbody>
</table>

Once all problems for habitats were ranked it became possible to assess these problems by category across all habitats. A matrix of habitat types and problem categories was developed (Salafsky et. al. 2003). This matrix allowed the Integration Team and Conservation Strategy Review team to identify priority problems at the state level.

This assessment helped identify the scope problems across habitats. Broad scale problems, those impacting multiple habitat categories, were addressed by the Integration Team through state level conservation strategies.

**Landscape Classification & Ecological Divisions**

Where available distribution of SGCN was recorded by biophysical region (Girton & Capen 1997) and 8-digit watersheds (NRCS 2003). Implementation of the Action Plan will include the development of baseline information the distribution and abundance of SGCN, and on amount,
location, condition and status of habitat within each biophysical region. These landscape units were selected in part because they will integrate well with other conservation efforts within the state and regionally. In its guidance to states, IAFWA recommended the use of Bailey's Sections for landscape classification (Bailey 1995, Bailey 1998). Biophysical regions can be considered a sub-unit of the Bailey's section providing finer grain detail. Data can be integrated into Bailey's sections to aide in regional, national and international conservation efforts.

Vermont's Species of Greatest Conservation Need

Vermonters love their wildlife. And wildlife love Vermont. During the past century many wildlife species once rare or missing from the state have returned in larger numbers. The resurgence of Vermont’s forests is a significant reason. From a low of 40% forest cover in the 1840s the state is now 78% forested. However, more trees are not the whole story. Restoring wildlife to the state also required the hard work and dedication of scientists, wildlife and habitat managers, sportsmen and other conservationists. Signature species such as deer, moose, beaver, fisher, osprey, peregrine falcon and loon, all missing or in perilously low numbers just decades ago are now faring well.

Keeping wildlife populations healthy offers a host of benefits: healthier ecosystems upon which we all depend, more wildlife to enjoy; and, fewer species on the brink of extirpation means fewer regulatory mandates.

Our work, however, is not complete. A significant number of wildlife species need attention to avoid new threats such as habitat loss, fragmentation and degradation; invasive exotic species; unregulated collecting and harvesting by people; and even natural events that could contribute to the decline of a species.

The State Wildlife Grants program is helping Vermonters meet these new challenges. Created by Congress in 2001 it provides federal funds for conservation to prevent fish and wildlife populations from becoming endangered. Per Congressional requirements, the Wildlife Action Plan is centered on the identification and conservation of "Species of Greatest Conservation Need" (SGCN).

Selecting SGCN

Vermont’s list of Species of Greatest Conservation Need includes 144 vertebrate species (of 470 in the state) and includes game and non-game species, 192 invertebrate species (of an estimated 15,000-36,000) and 577 plant species (of an estimated 2000 vascular and non-vascular plant species).

In Vermont, six Action Plan Species Teams, with expertise in birds, fish, invertebrates, mammals, plants and reptiles & amphibians, met frequently between May and September 2004 to assess the status of Vermont's wildlife. They employed assessment criteria developed by the interdisciplinary Action Plan Integration Team to aid and normalize SGCN selection. Criteria included the degree of species rarity, species designated as at-risk, population trends, species whose habitat are vulnerable to loss, habitat fragmentation, habitat conversion or succession changes and species threatened by exotic plants or animals.

Teams used the best information available at the time from local, regional and national sources. However, while a wealth of information is available for some species; others (especially invertebrates, fish, small mammals and some reptiles and amphibians) are poorly known. Species were ranked with a conservation priority of high, medium or low. Those ranked medium and high constitute Vermont's Species of Greatest Conservation Need. Those ranked low priority are considered reasonably secure. It is expected that low priority species will benefit from
conservation efforts directed toward species ranked medium and high as well as from other ongoing wildlife management programs (e.g., federal aid to sportfish and wildlife).

Ongoing wildlife monitoring required by the State Wildlife Grants program will help track species and strategy progress toward greater security. Regularly scheduled Action Plan review and revision will provide opportunities to add additional species to the list as warranted and to remove those species deemed secure.

Details of the Species of Greatest Conservation Need selection process can be found in Chapter 3: Developing the Vermont Action Plan.

**Plant SGCN**

Vermont's plant SGCN list includes 577 of approximately 2,000 vascular and non-vascular plants found in the state. This list includes all species ranked S1 (critically imperiled) and S2 (imperiled) and a very few others that warrant concern. Those SGCN also on the New England Plant Conservation Program list of regionally rare plants will be ranked High Priority. All others were ranked medium priority. Plants are not eligible for SWG funds. The plant list can be found in appendix A6.

**Use of and Changes to this List**

The list of Species of Greatest Conservation Need will help prioritize the allocation of State Wildlife Grants funds and other conservation funds. The list will also provide a quick measure of our success conserving Vermont's wildlife. It should be noted that the SGCN list is not the same as the State or Federal Endangered Species List and should not be construed to function as one. Some of the species on the list may be relatively common including some game species. It is our goal to keep them that way.

The Species of Greatest Conservation Need list can be amended if and when important information becomes available about a species’ status. For example, there are a number of current and pending inventory and assessment projects funded by State Wildlife Grants that could significantly increase our understanding of a species’ status.

**Big Game: White-Tailed Deer, Moose & Wild Turkey**

Nearly 20 game and sportfish species are listed on the following pages as Species of Greatest Conservation Need (SGCN) due to concerns about population declines and loss of habitat. White-tailed deer, moose and wild turkey, however, were not selected as SGCN. Though absent or nearly extirpated from the state by the 1865, their populations are now sufficiently large and stable. And, relative to SGCN, our knowledge of deer, moose and turkey biology and management is great.

White-tailed deer, moose and wild turkey rank high among Vermont's greatest wildlife restoration successes. Still their management remains of utmost concern because of the great importance they have to Vermonters and because of the significant roles they play in their ecosystems. Fortunately, management plans (developed with significant public involvement), harvest regulations and monitoring protocols have long been in place for these species and dependable implementation funds come through license fees and the Federal Aid to Wildlife Restoration Act.

For more information about deer, moose and wild turkey go to [http://www.vtfishandwildlife.com](http://www.vtfishandwildlife.com)

Vermont's Species of Greatest Conservation Need

**Invertebrates** 192 of an estimated 15,000 to 36,000 Vermont invertebrate species.

**Odonata** (Dragonflies & Damselflies) (41)

- **Bog/Fen/Swamp/Marshy Pond Odonata Group+** (20)
  - Southern Spreadwing (Lestes disjunctus australis)
  - Subarctic Bluets (Coenagrion arcticum)
  - Citrine Forktail (Ischnura hastata)
  - Comet darner (Anax longipes)
  - Mottled Darner (Aeshna elegans)
  - Zigzag Darner (Aeshna seticollis)
  - Subarctic Darner (Aeshna subarctica)
  - Green-striped Darner (Aeshna verticalis)
  - Spatterdock Darner (Aeshna mutata)
  - Swamp Darner (Epiaeschna heros)
  - Harlequin Darner (Gomphaeschna furcata)
  - Cyrano Darner (Nasiaeschna pentacantha)
  - Petite Emerald (Somatochlora lutea)
  - Painted skimmer (Libellula semicorporata)
  - Ski-tailed Emerald (Somatochlora elongata)
  - Forcipate Emerald (Somatochlora forcipata)
  - Delicate Emerald (Somatochlora franklini)
  - Kennedy's Emerald (Somatochlora kennedyi)
  - Ebony Boghaunter (Williamsonia fletcheri)
  - Black Meadowhawk (Sympetrum danae)

- **Wetlands Odonata Group+** (7)
  - New England bluet (Enallagma laterale)
  - Vernal Bluet (Enallagma vernale)
  - Slender Bluet (Enallagma trissium)
  - Ringed Emerald (Somatochlora albicincta)
  - Lake Emerald (Somatochlora eingultata)
  - White Corporal (Libellula excisa)

- **Lakes/Ponds Odonata Group+** (7)
  - American rubspot (Hetaerina americana)
  - Blue-fronted dancer (Argia apicalis)
  - Rainbow bluet (Enallagma antennatum)
  - Spine-crowned clubtail (Gomphus abbreviatus)
  - Rapids clubtail (Gomphus quadricolor)
  - Skillet clubtail (Gomphus ventricosus)
  - Cobra clubtail (Gomphus hirtus)
  - Brook skimmer (Ophiogomphus aspersus)
  - Riffle skimmer (Ophiogomphus carolus)
  - Maine skimmer (Ophiogomphus mainensis)
  - Rusty skimmer (Ophiogomphus rupinsulensis)
  - Stygian shadowdragon (Neurocordulia yamaskanensis)

+ Note that each Odonata species was assigned to a single community type, even though there is sometimes overlap suggested by the description of habitat

**Lepidoptera** (Butterflies & Moths) (33)

- **Wetland Butterflies Group** (7)
  - Bog copper (Lycaena epixanthe)
  - Jutta arctic (Oeneis jutta)
  - Dion skipper (Hesperia melpomene)
  - Black dash (Euphyes conspicua)
  - Two-spotted skipper (Euphyes bicolor)
  - Mulberry wing (Poanes massasaquit)
  - Broad-winged skipper (Poanes viator)

- **Grassland Butterflies Group** (4)
  - Cobweb skipper (Hesperia metea)
  - Persius duskywing (Eumenis persius)
  - Regal fritillary (Speyeria idalia)
  - Dusted Skipper (Atrytonopsis hianna)

- **Hardwood Forest Butterflies Group** (5)
  - West Virginia white (Peris virginiensis)
  - Early hairstreak (Locarla laeta)
  - Hackberry emporer (Asterocampa celtis)
  - Tawny emporer (Asterocampa clyton)
  - Edwards' hairstreak (Satyrium edwardsii)

- **Mayflies/Stoneflies/Caddisflies Group** (8)
  - A Mayfly (Ameletus browni)
  - A Mayfly (Ameletus tertius)
  - Tomah Mayfly (Siphlonisca aerodromia)
  - Roaring Brook Mayfly (Epeorus frisoni)

**Moths Group** (17)

- A Ghost Moth (Sthenopis thule)
- Currant Spanworm (Itame ribearia)
- Imperial Moth (Eacles imperialis pini)
- New England Buckmoth (Hemileuca lucina)
- Hermit Sphinx (Sphinx eremitus)
- Plum Sphinx (Sphinx drupiferarum)
- Clemens' Sphinx (Sphinx leucitosa)
- A Noctuid Moth (Xestia (Anomogyna) fabulosa)
- A Noctuid Moth (Lasionycta taigata)
- A Noctuid Moth (Lemmeria digitalis)
- Fraenkel's Lithophane (Lithophane fraenkeloni)
- An Autumnal Noctuid Moth (Pachypolia atricornis)
- Ostrich Fern Borer Moth (Papaipema sp. 2)
- A Noctuid Moth (Propergea sp. 1 (P. costa))
- A Noctuid Moth (Xestia homogena)
- Pine Barrens Zanclognatha (Zanclognatha martha)
- A Noctuid Moth (Zale submediana)

A Mayfly (Eurylophella bicoloroides)
A Mayfly (Baetisca rubescens)
A Stonefly (Alloperla voiae)
A Caddisfly (Rhyacophila brunnea)
Invertebrates, continued

**Tiger Beetles Group (6)**
- A Tiger Beetle (Cicindela anecosconensis)
- Cobblestone Tiger Beetle (Cicindela marginipennis)
- A Tiger Beetle (Cicindela patruela)
- Puritan Tiger Beetle (Cicindela puritana)
- Beach-dune tiger beetle (Cicindela hirticollis)
- Long-lip Tiger Beetle (Cicindela longilabris)

**Ground Beetle Group (Carabidae) (73)**
- Sphaeroderus nitidicollis brevoorti
- Acupalpus rectangulus
- Pericompus ephippatus
- Platynus cineticollis
- Platynus parmagnatus
- Platypatrobus lastrinus
- Schizogenius ferrugineus
- Sericola obsolata
- Sericoda quadripunctata
- Tetragonoderus fasciatus
- Trichocellos cognatus
- Atranus pubescens
- Amara laevipennis
- Amara erratica
- Ananchomenus picitornis
- Anisopus latens
- Blethias quadricollis
- Blethia julii
- Carabus goryi
- Carabus macander
- Dicaeus dilatus
- Dicaeus teter

**Mollusca (27)**

**Freshwater Mussels Group (13)**
- Eastern pearlshell (Margaritifera margaritifera)
- Dwarf wedgemussel (Alasmidonta variocosa)
- Brook floater (Alasmidonta varicosa)
- Pocketbook (Lampsilis ovata)
- Fluted-shell (Lasmigona costata)
- Creek heelsplitter (Lasmigona compressa)
- Pink heelsplitter (Potamilus alatus)
- Fragile papershell (Lepotidea fragilis)
- Black sandshell (Ligumia recta)
- Giant floater (Pyganodon grandis)
- Cylindrical papershell (Anodontoides ferussacianus)
- Alewife floater (Anodontoides foveolatus)

**Snails Group (14)**
- Fingered valvata (Valvata lewisi)
- Mossy valvata (Valvata sincera)
- Squat duskysnail (Amnicola (Lyogyrus) grana)
- Canadian duskysnail (Amnicola (Lyogyrus) walkeri)
- Buffalo pebblesnail (Gillia altilis)
- Pupa duskysnail (Lyogyrus (Amnicola) pupoidea)
- Boreal marstonia (Marstonia (Pyrgulopsis) decepta)
- Liver elminia (Goniobasis livescens)
- Sharp hornsnail (Pleurocera acuta)
- Spindle lymnaea (Acella haldemani)
- Mammoth lymnaea (Bulimnea megastoma)
- Country fossaria (Fossaria rustica)
- Disco gyro (Gyraulus circumstriatus)
- Star gyro (Gyraulus cristata)

**Crustaceans Group (3)**
- An Amphipod (Diporeia hoyi)
- Taconic Cave Amphipod (Stygobromus borealis)
- Appalachian brook crayfish (Camburus bartonii)

**Ant Group (1)**
- A Slave-making Ant  Leptothorax sp. 1 (L. pillagens)
Problems Impacting Species of Greatest Conservation Need

Element number three of the eight congressionally required elements of a Wildlife Action Plan requires that states: describe the problems that may adversely affect Species of Greatest Conservation Need or their habitats and priority research and survey efforts needed to identify factors which may assist in restoration and improved conservation of these species and habitats. For the purposes of this report "problem" is defined as follows:

Problem: A force causing a negative impact at the species, population, habitat and landscape levels (e.g., habitat conversion, pollution, illegal pet trade). A problem can also be the lack of information or a data gap vital to the successful management of a species.

For each Species of Greatest Conservation Need in the Action Plan we identified priority problems. Priority research needed to evaluate other potential problems was also identified. Problems are detailed in short narrative descriptions in each species summary (Appendix A) in each habitat/community summary (Appendix B).

Each of the problems identified in the Action Plan was assigned to one of 22 categories roughly grouped into habitat-related factors and non-habitat-related factors. These categories make it possible to search our database for similar factors impacting other species. It also makes it easier to organize and create summaries for broad scale conservation planning. The problem categories were developed by the U.S. Forest Service during the current Forest Plan Revision for the Green Mountain National Forest.

The 22 categories are not mutually exclusive and problems can often logically be placed into more than one category depending on the particular stress it causes for a species or habitat. For example, a road can fragment the habitat of grassland nesting birds, cars traveling the road can squash amphibians crossing the road to mate in an adjacent stream, and salt spread on the road to prevent icing can wash into that stream impacting its population of brown trout. In this example the problems stemming from the road would be recorded in the "Habitat Fragmentation," "Impacts of Roads & Trails," and "Pollution" categories.

Problems are often species and/or habitat specific. What may negatively impact one species may benefit another. For example, if a cold water stream with a healthy brook trout population was dammed it might no longer support brook trout. That impact of the dam would be described as the "conversion of habitat" category. However, the reservoir created by the dam might make it more suitable for a warm water fish species.

Clearly life is too complex to be stuffed into any one box. Therefore it is important to read the full description of a factor affecting a species or habitat in the appropriate species or habitat summary. Definitions for these factors can be found in Appendix C.
Problem Categories
See Appendix C for definitions of each category. See Appendix A-SGCN summaries and Appendix B-habitat/community/landscape summaries for context.

Habitat-Related Problem Categories
- Climate Change
- Habitat Alteration/Degradation
- Habitat Conversion
- Habitat Fragmentation
- Hydrologic Alteration
- Impacts of Roads and Trails
- Inadequate Distribution of Successional Stages
- Inadequate Disturbance Regime
- Invasion by Exotic Species
- Sedimentation

Non-Habitat-Related Problem Categories
- Competition
- Disease
- Genetics
- Harvest or Collection
- Incompatible Recreation
- Loss of Prey Base
- Loss of Relationship with Other Species
- Parasitism
- Pollution
- Predation or Herbivory
- Reproductive Traits,
- Trampling & Direct Impacts
SGCN Conservation Strategy Development

Element number four of the eight congressionally required elements of a Wildlife Action Plan requires that states describe “conservation actions proposed to conserve the identified species and habitats and priorities for implementing such actions.”

We identified strategies to address the problems impacting each of Species of Greatest Conservation Need (SGCN) and habitats in the Action Plan. Strategies identified in the Action Plan are based on the best science available today as well as our strategic assessment of needs and priorities of all wildlife species. In the coming years, as monitoring data on SGCN and conservation actions becomes available, as priorities change, or new problems or opportunities arise, strategies may need to be revisited. Not every strategy in this report will be eligible for State Wildlife Grant funding. Furthermore, it may not be suitable, or feasible, for the Vermont Fish & Wildlife Department to implement some of the strategies in this report, however, some conservation partners may find them fitting and practical.

Strategies are described in the Action Plan in short narratives in each species summary and in each habitat, community and landscape summary. Strategies are intentionally broad, directional, and nonspecific so as not to constrain our selection of actions for implementing them. For example, a strategy such as “provide technical assistance to landowners to maintain or improve riparian habitat for Species of Greatest Conservation Need” allows for different approaches to providing that assistance and leaves the door open to a variety of providers to implement. Where strategy implementation is to be funded by the State Wildlife Grant program the approach should be consistent with the Department’s mission and strategic plan, and precise procedures will be detailed in operational plans once the Action Plan is finalized.

Vermont’s Action Plan was designed to be a strategy for the state, not just the Fish & Wildlife Department. While the department may be responsible for implementing many of the strategies in this report, it will be conservation partners, however, that may be the more logical and appropriate leaders for others, due to their skills and expertise, staffing, history, location, available resources and constituencies.

Each of the strategies identified in the Action Plan were assigned to one of 27 categories in six major classes. The categories were developed by the Conservation Measures Partnership (Salafsky 2005) as a means to standardize terminology (not practices) among conservation practitioners worldwide. Many states have used these same categories to organize the strategies and actions in their Action Plan.

It should be noted that the categories are used solely for the purpose of organizing and grouping strategies developed by Action Plan teams and committees. It was not our goal to create strategies for every category. A few categories were not applicable to the species or habitats in Vermont whereas others were deemed not as effective. Definitions for each strategy can be found in Appendix C.
Conserving Vermont's Birds

Birds Team
Cedric Alexander, Vermont Fish & Wildlife Dept. (team leader)
Eric Derlath US Fish & Wildlife Service
Patrick Doran, Wildlands Project
Dave Frisque, US Fish & Wildlife Service
Margaret Fowle, National Wildlife Federation
John Gobeille, Vermont Fish & Wildlife Dept.
Paul Karczmarczyk, Ruffed Grouse Society
Mark Labarr, Audubon Society
Chris Rimmer, Vermont Institute of Natural Science
Dr. Allan Strong, University of Vermont

Team Charge
The Bird was charged with identifying Species of Greatest Conservation Need (SGCN); describing the distribution and habitat usage for each SGCN; evaluating problems impacting SGCN and their habitat; identifying priority research needs to improve our ability to conserve these species; and, developing conservation strategies to address priority problems. Details of Species Team and other Action Plan team and committee charges can be found in Appendix D of this document.

Introduction
The Vermont Fish and Wildlife Department convened the Action Plan Bird Team in May 2004. The 9-member team was composed of biologists from the VFWD, USFWS, UVM Co-op Unit, and 5 non-profit conservation organizations. The team met a total of 8 times over the ensuing 12 months. The Department is very grateful for the many days of work team members contributed to attend meetings, research and prepare spreadsheets and reports, and consult with one another between meetings.

Selecting Bird SGCN
In contrast to lesser-known taxa, the bird team benefited from the relative wealth of available data on bird distribution and abundance. Data from Vermont’s original and current Breeding Bird Atlases and the USFWS Breeding Bird Surveys helped immensely in selecting our 57 SGCN. In addition to these actual data sources, ongoing bird conservation programs, including the Vermont Endangered Species Scientific Advisory Group on Birds SAG-B), Partners-In-Flight, North American Bird Conservation Initiative, National Audubon Society’s Watch List, and the American Bird Conservancy’s Green List all contributed to our understanding of which species belonged on Vermont’s SGCN list.

Selection criteria included knowledge about current listing as endangered or threatened, population declines, rarity, vulnerability of habitat, life history traits, impacts from humans, and recent range expansion or contraction. Each species was examined across all criteria and the team developed a high, medium, and low conservation need ranking to attempt to separate species with greater need from those that may be more secure, at least in the short term.
Bird species rare in Vermont did not always make the SGCN listing. Species that have expanded their range in recent decades due to a proliferation of winter bird feeders, such as Tufted titmouse, were excluded, as we did not consider Vermont to be a geographic area of responsibility for that species. Other species for which Vermont is on the extreme periphery of their breeding range, and for which confirmed breeding records are very infrequent, such as the three-toed woodpecker, were also not selected. These ‘filtering’ methods are consistent with the work of Vermont’s SAG-B (see Chapter 3: Developing Vermont's Action Plan, for details on selection criteria and process).

Full reports on each Species of Greatest Conservation Need are in Appendix A of this document. The following is a summary of those reports.

**Birds and Their Habitat Needs**

Vermont’s bird SGCN utilize a variety of habitats from open and shrub-dominated wetlands, mature hardwood or coniferous forests, young regenerating forests, old fields, grasslands, and other cultural habitats such as buildings and structures. As birds are generally more mobile relative to most species from other taxa, they are usually better able to exploit smaller, more widely distributed habitat patches. However, most species benefit from the larger assemblages of similar habitat types, such as a contiguous forest area or large, agricultural (grassland) complex.

The Bird Team organized most birds into one of several habitat guilds, for which a particular conservation strategy would often be appropriate for all species in the guild. These guilds match the major habitat categories used in this report (see the section titled SGCN Conservation at Multiple Scales later in this chapter):

- Northern hardwood forest & Oak-pine-northern hardwood forest
- Spruce-fir northern hardwood forest
- Sub-alpine krummholz & Montane spruce-fir forests (high elevation areas)
- Early successional forest stages
- Riparian
- Lacustrine (lakes and ponds)
- Wetlands-(open, shrub and forested wetlands)
- Cliff & Talus
- Grassland
- Grassland/Edge
- Urban

**Discussion of Problems Impacting Bird SGCN**

The problems identified most frequently as problems for Vermont's bird populations are all related to changes in habitat: conversion of habitat (49 SGCN), habitat alteration (31), habitat fragmentation (27), and distribution of successional stages (27). Many bird species find optimum habitat in young regenerating forests, which have declined statewide in recent decades. Similarly, grassland-dependent species, which are declining throughout the northeast, are finding less and less suitable habitat in Vermont as farms are managed more intensively, or sold and either developed or reverted to forestland. Increased roads, housing
units, free-roaming pets, and other attendant disturbances further fragments habitat to the
detriment of most species. See appendix A for full reports on each SGCN.

Research & Monitoring Needs and Conservation Strategies
The research and monitoring needs and conservation strategies most frequently identified by
the Bird Team and those best applied for multiple bird SGCN are as follows:

Research & Monitoring Needs
1. Better determine habitat requirements and habitat availability.
2. Better determine the distribution and relative abundance of populations in Vermont.
4. Obtain better knowledge of basic life history traits.

Conservation Strategies
1) Habitat Restoration via efforts on public lands and conservation payments or other
financial incentives, fee simple purchase, easements, management guidelines, and
cooperative agreements with user groups and private landowners. Existing technical
assistance/cost-share programs (WHIP, LIP, CRP) were frequently identified as potential
funding sources to implement conservation on private lands. Important Bird Area
designations can aid in the development of needed funds. Common habitat restoration
themes include incentives and planning to slow the rate of fragmentation and development
and maintain blocks of contiguous forest, grasslands, early and late-successional habitats.

2) Species Restoration projects, which may involve active translocation of individuals or eggs
from a source population into suitable Vermont habitats, and/or may involve efforts to
provide suitable nesting sites and reduce predation or human disturbances around nesting
sites.

3) Raising awareness within the general public to build support and opportunities for
conservation techniques. Important Bird Area designations can help focus public attention
on opportunity areas.

4) Developing and evaluating forestry practices that can enhance habitat suitability such
as maintain or increasing aspen stands or the retention of coarse woody debris and
snags. Provide technical assistance to landowners and communities about best
management practices.

5) Initiate an international effort to maintain large blocks of undeveloped forests linked
together by habitat corridors in order to provide a network of interconnected
habitats throughout northeastern New England and southeastern Canada.

6) Identify, prioritize and maintain existing contiguous forest blocks and associated linkages
that allow for upward and northward movement in response to climate change.

7) Participate in existing regulatory processes (e.g., Act 250) to protect and restore
critical habitats.

See Appendix A for full reports on each bird Species of Greatest Conservation Need.
Conserving Vermont's Fishes

Team Charge
The Fish Team was charged with identifying Species of Greatest Conservation Need (SGCN); describing the distribution and habitat usage for each SGCN; evaluating problems impacting SGCN and their habitat; identifying priority research needs to improve our ability to conserve these species; and, developing conservation strategies to address priority problems. Details of the Species Teams and other Action Plan team and committee charges can be found in Appendix D of this document.

Introduction
Vermont with its estimated 7,100 miles of rivers and streams and 809 lakes and ponds supports populations of 92 fish species (Langdon et al. in press). Eighty of these are recognized as being native to the state. A native species is one that was present in the state prior to early European colonization. The remaining 12 species are non-indigenous to Vermont. These fishes were either purposely introduced, legally and illegally, to waters of the state, such as for sport fish enhancement (e.g., brown and rainbow trout), or gained access inadvertently to the state via interstate waterways, such as canals (e.g., gizzard shad). Lake Champlain has the most diverse fish community of any Vermont water with about 71 species documented to exist there.

Vermonters are probably aware of the existence of about one third of the fish species occurring in the state. Our familiarity with most of these fishes is rooted in sport fishing; that is, their recognized value as game fish and to a lesser degree their use as bait fish. As for the remaining two-thirds of Vermont species, many exist here largely out-of-sight of the general public and others are viewed more or less with ambivalence. Nonetheless, the diversity of Vermont's ichthyofauna contributes significantly to the functional ecological complexity of our aquatic systems. Many species are excellent indicators of the health of our environment, such as their sensitivity to toxic chemicals (e.g., mercury and PCBs) and habitat change. Additionally, sport fisheries, utilized and valued by the public, are dependent directly and indirectly on healthy communities and ecosystems.

Native fishes face many conservation challenges. The threats of habitat alteration, loss and fragmentation are pervasive in Vermont's rapidly changing landscape. The introduction of non-indigenous fishes, including associated aquatic pathogens and parasites, also pose risks to aquatic ecosystem health and native species conservation. Just within the past 20 years, seven non-native fishes have shown up in state and interstate waters. Whirling disease, caused by the parasite *Myxobolus cerebralis*, first appeared in native brook trout inhabiting Vermont sections of the
Batten Kill as recently as 2002. Two viral diseases have also recently appeared in Vermont waters. Largemouth bass virus was first detected in Lake Champlain in 2002 and a year later in Lake St. Catherine; and esocid lymphosarcoma infecting Lake Champlain northern pike in 2002 (http://www.vtfishandwildlife.com/fisheries_health.cfm). Unregulated or illegal transportation of fishes from out-of-state sources and between in-state waters is likely cause for the increasing incidences of disease-causing organisms appearing in Vermont fish populations.

**Fish SGCN Selection**

Selection criteria included 27 categories reflecting our knowledge about current listing as endangered and threatened; species rarity; population declines; vulnerability of habitats; life history traits; vulnerability to collection, harvest or other taking; other impacts from humans; and dispersal capability. Only native species were considered. Each species was examined across all criteria by the eight-person team. Based on this evaluation process the team assigned a high, medium and low rank to attempt to separate species with greater conservation needs from those with more secure status, at least in the short term. See chapter 3 of this report, “Developing Vermont’s Action Plan,” for details on selection criteria and process. This approach resulted in 33 species making either the rank of high conservation need or medium conservation need.

**High Conservation Need:** Northern brook lamprey, American brook lamprey, lake sturgeon, American eel, brassy minnow, bridle shiner, blackchin shiner, blacknose shiner, quillback, silver redhorse, greater redhorse, stonecat, muskellunge, anadromous Atlantic salmon, arctic char, eastern sand darter, channel darter, and sauger.

**Medium Conservation Need:** Silver lamprey, sea lamprey (Connecticut River basin population only), mooneye, blueback herring (Connecticut River basin population only), American shad, shorthead redhorse, redfin pickerel, cisco or lake herring, lake whitefish, round whitefish, landlocked Atlantic salmon, brook trout (naturally reproducing populations only), lake trout (naturally reproducing populations only), mottled sculpin, and redbreast sunfish.

Species of Greatest Conservation Need status for two species, sea lamprey and blueback herring, are limited to specific populations within the state, i.e. populations residing in the Connecticut River basin. Similarly, lake trout and brook trout are defined with limitations. One species, the arctic char, is believed to be extirpated. (It should be noted that Connecticut River sea lamprey are not parasitic in freshwater, and that neither northern or American brook lamprey species are parasitic).

Although a disproportionate number of Vermont’s SGCN are at the periphery of their range, this should not diminish the importance of these species to the state’s biodiversity or in terms of their ecological significance. To illustrate this, of the 80 native Vermont fish species, nearly half of these are here on the eastern edge of each of the species’ natural North American range.

Full reports on each Species of Greatest Conservation Need are in Appendix A of this document. The following is a summary of those reports.
Habitat Needs
Vermont’s fish species use a variety of habitats: small ponds, large lakes, rivers, streams, and wetlands. Some habitats are used year round and others are occupied seasonally, such as while spawning. Within water bodies, SGCN have specific habitat needs for example, riffles or pools in streams or deep, cold areas of lakes. Loss or degradation of any one critical habitat component can threaten the survival of the species in that particular water.

While most of our fishes are completely freshwater dependent, others spend portions of their lives in both freshwater and marine environments. Four SGCN (American eel, blueback herring, American shad and sea-run Atlantic salmon) are dependent on both. Herring, shad and salmon have anadromous life cycles, that is spawning and at least a portion of the juvenile life occurs in freshwater; to attain maturity the fish must go to sea for a period of years. In contrast, eel are catadromous. Maturity is attained in freshwater and reproduction occurs in the ocean. Consequently, whether anadromous or catadromous, these species are not only are faced with problems at the Vermont landscape level but also those at the regional and international scopes. To conserve our native fishes, and in particular SGCN, it is essential that we protect, enhance and restore habitat degradation and loss not only within Vermont but also, where appropriate, beyond our borders.

Discussion Problems Impacting Fish SGCN
Factors affecting the security of SGCN are classified as either habitat or non-habitat problems. The most frequently identified habitat related problems impacting aquatic systems are habitat alteration, habitat fragmentation, habitat conversion, invasive non-indigenous species, and climate change. Habitat alteration includes activities, which diminish the quality and/or quantity of habitat features critical to the survival and maintenance of fish populations and other biota on which SGCN are dependent, including stream flows and lake water levels, water temperature regimes, and habitat diversity. Sedimentation is a form of habitat alteration by which the composition of the stream or lake bottoms are altered by greater than normal deposition of fine materials (e.g., silt, sand, organic matter) changing the composition and suitability of substrates to the detriment of their spawning, cover and food production values. Habitat conversion results in the total or near complete loss of function as a result of extreme habitat alteration. Examples of habitat conversion are loss of active flood plains, wetland draining and on-stream impoundments. Habitat fragmentation occurs when artificial structures, such as dams, impassable bridge structures, and dewatered stream channels, interfere with the movements of fish preventing their access to critical spawning areas or seasonal refugia. Habitat fragmentation also interferes with the natural dispersal of fish and genetic flow within and between populations. Climate change threatens several SGCN at the regional scale by altering (warming) their required thermal regimes. Invasive species, such as nonnative aquatic plants and zebra mussels, can impact aquatic habitats in a variety of ways. Exotic plants represent a “double edged sword” with respect to the conservation of certain fish species requiring abundant aquatic vegetation. Invasive plant species, such as Eurasian milfoil, may displace native plant communities on which fish are dependent for refugia, food production, and spawning. And, on the other hand, invasive vegetation control programs may eliminate these functions before native plants are restored to desired levels.

While virtually all fishes identified as SGCN are impacted by one or more problems to their habitats, non-habitat related problems are generally more variable from species to species. In
some cases, non-habitat problems are a consequence of impacts on habitat. Those affecting SGCN include competition from other species, predation, loss of prey base, water pollution, disease and parasites, and over-harvest. The sea lamprey problem in Lake Champlain poses a challenging dilemma. Sea lamprey has been identified as a known or potential parasite/predator on several SGCN. On the other hand, other SGCN may be threatened by certain control methods needed to control sea lamprey abundance and parasitism rates in the lake. Further research and monitoring is required to ensure that successful control measures minimize harm to SGCN.

**Research & Monitoring Needs and Conservation Strategies**

The Fish Team identified priority research and monitoring projects and needs to improve our ability to conserve Vermont’s fish SGCN. The Team also developed conservation strategies to address problems impacting each SGCN. Those cited most frequently and those most effectively applied for multiple fish SGCN include:

**Research & Monitoring Needs**

1. Better determine the distribution and relative abundance of populations in Vermont.
2. Acquire better information on species’ life histories, biology and habitat requirements.
3. Monitor and assess populations and habitats for current condition and future changes.
4. Identify and monitor problems for species and their habitats.
5. Establish a centralized fish database within the Agency of Natural Resources to manage fish and other aquatic data, track permits and management projects that impact aquatic species.

**Conservation Strategies**

1. Protect and restore aquatic and riparian habitats through improved water quality; flow, water level and temperature regimes; sediment reduction; establishment of streamside buffers (see ANR buffer policy); and suitable aquatic habitat structure, diversity and complexity.
2. Maintain and restore aquatic organism passage and habitat connectivity at barriers (e.g., dams, culverts) to provide access to critical habitats and maintain ecological connectivity.
3. Assess, monitor and manage as appropriate potential negative and beneficial effects of the Lake Champlain sea lamprey control program on SGCN and other non-target fishes.
4. Participate in existing regulatory processes (e.g., Act 250, stream alteration permits) to protect and restore critical habitats.
5. Implement measures and programs to prevent the introduction and expansion of non-indigenous species to Vermont waters; develop and execute appropriate invasive species control programs.
6. Support and cooperate with inter-agency programs for the restoration of anadromous and catadromous fishes to the Connecticut River basin.
7. Support efforts to curb global warming and its negative impacts on SGCN.
8. Support state and regional efforts to require reduction in emissions from coal burning power plants and other sources of acid precipitation.

See Appendix A for full reports on each fish Species of Greatest Conservation Need.

Team Charge
The Invertebrate Team was charged with identifying Species of Greatest Conservation Need (SGCN); describing the distribution and habitat usage for each SGCN; evaluating problems impacting SGCN and their habitat; identifying priority research needs to improve our ability to conserve these species; and, developing conservation strategies to address priority problems. Details of Species Team and other Action Plan team and committee charges can be found in Appendix D of this document.

Introduction
The role of invertebrates in our world is fairly unrecognized by humans. But once we get beyond the buzz of mosquitoes and our annoyance with blackflies, our reliance upon these tiny animals slowly unfolds. Within cool forest streams, stonefly and mayfly nymphs consume leaves that fall from forest trees and provide a food source for brook trout and other fishes. In the gardener's corner, bees, flies, wasps, and butterflies pollinate the flowers that will later yield the anticipated fruits and vegetables. Spiders wait to ambush flies in our homes. Dragonflies patrol the stream shores for their insect prey. Beetles, flies, and other invertebrates consume the wastes produced by the human world, leaving fertile soil in exchange. Mostly unnoticed and even avoided these smallest of creatures serve an amazing array of functions that we depend upon in our everyday life. The diversity of species we are so fortunate to have is, itself, something to marvel.

Of the thousands of species that occur in Vermont, several are rare or threatened enough to be at risk of disappearing from the state in the future. The causes that lead to their predicament vary among species. One of the greatest obstacles in taking action to help conserve these “at risk” invertebrates is the scarcity of information that exists on their distribution, abundance, habitat requirements, life history characteristics, population trends, and threats. It is necessary to assess the status and needs of each species to adequately conserve populations and track the success of these actions. Obtaining baseline information is, therefore, included as a component of actions to be taken for invertebrate SGCN (Appendix A).

Selecting Invertebrate SGCN
The task of assessing the conservation needs of Vermont’s invertebrates is daunting. The number of species that occur within the state is not known; however, estimates for insects alone have ranged 15,000 to 20,000 different species. In addition, many of our invertebrates have not yet been scientifically described. Life history, distribution, and abundance
information is available for a small minority of Vermont’s invertebrates that would be considered as conservation targets, such as freshwater mussels and some tiger beetles. Thus the Invertebrate Team had to determine how best to assess conservation needs with limited information to draw upon. State and regional experts, as well as entomological hobbyists, have compiled a valuable knowledge base for selected groups of invertebrates over the last century. Although distributional information is often limited, an understanding of the natural history of many of these species enabled the team to move forward. It was the team’s decision that identification of SGCN would focus on species and species groups for which adequate information was available. The following invertebrate groups were reviewed while compiling the SGCN list:

- Dragonflies and Damselflies (Odonata)
- Butterflies and Moths (Lepidoptera)
- Mayflies (Ephemeroptera)
- Stoneflies (Plecoptera)
- Tiger Beetles (Carabidae, in part)
- Caddisflies (Tricoptera, in part)
- Freshwater Mussels and Freshwater Snails (Mollusca, in part)
- Invertebrates currently considered to be rare within Vermont

SGCN selection criteria included knowledge about: current listing as endangered and threatened; population declines; rarity; vulnerability of habitat; life history traits; vulnerability to collection or take; population limitations; regional status; historic occurrence; disjunct populations; habitat specialization; impacts by exotics; and dispersal capability. A review using these criteria resulted in a SGCN list of 192 species. It is the Invertebrate Team’s expectation that, as available information on invertebrates increases, future iterations of the Action Plan will include a review of more taxa to be considered in the SGCN list.

Full reports on Invertebrate Species of Greatest Conservation Need are in Appendix A of this document. The following is a summary of those reports.

**Habitat Needs**

As invertebrates are the most diverse of Vermont’s animals, the breadth of habitats they occupy is great. From deep lakes and slow rivers to the alpine peaks of our highest mountains, from the leaf litter of lowland floodplain forests to treetops in upland beech stands, there are invertebrates utilizing an amazing array of niches in every corner of Vermont. Many of these species have fairly general habitat requirements, or live in natural communities that are common and secure within the state. A number of these are so abundant that they are treated as forest and agricultural pests. Such species do not normally require special conservation attention.

In contrast, habitat specialization is also a common strategy among invertebrates. Examples of habitats that host specialized invertebrates include fens, black spruce bogs, river cobble shores, large rivers, or alpine meadow. Herbivorous invertebrates will often feed on only a small number of plant hosts, exhibiting another form of specialization. While such specialization is often advantageous when the required habitat or plant host is plentiful, it
creates a risk to these invertebrates when the habitat or host is rare, widely scattered, or also at risk. In such cases, conservation attention is sometimes needed to ensure that these specialized invertebrates remain a part of Vermont’s fauna.

Certain habitats or areas of Vermont support highly diverse wildlife assemblages, including SGCN invertebrates. A good example is Lake Champlain and its lower tributaries, where many of our dragonfly and freshwater mussel SGCN are located. These species rich areas provide us the opportunity to help conserve many SGCN simultaneously.

**Discussion of Problems Impacting Invertebrate SGCN**

The greatest problems faced by SGCN invertebrates in Vermont relate to the loss, degradation, and fragmentation of their habitats. Poorly planned construction is ever-increasing on the landscape, often whittling away the wetland and upland habitats available to these creatures when these areas are not protected. As small habitat units disappear from the landscape, the remaining ones become more distant from one another; this presents an obstacle to those invertebrates that are limited to short-distance movement. Surface runoff from developed and agricultural lands can carry pollutant and sediment loads that find their way to rivers and streams, particularly during heavy rain events. The buildup of sediments on river bottoms embeds the natural substrate and can smother the invertebrates that reside there. Other pollutants entering streams and rivers can be detrimental to sensitive aquatic species.

Exotic species are having a negative impact on several invertebrate SGCN, and will likely present increased challenges to conservation in the future as new foreign species invade our lands and waters. Freshwater snails and mussels have been eliminated from several large areas of Lake Champlain due to zebra mussel invasion. A small exotic fly originally introduced to control gypsy moths has instead preyed upon many native woodland moth species, including some of our giant silk moths. This may prompt the need for future inclusion as SGCN such species as the lunar moth, polyphemus moth, and cecropia silkmoth.

Some of the challenges faced by SGCN invertebrates stem from their dwindling numbers and their natural life history characteristics. Low natural recruitment of offspring into the adult populations can hinder population recovery when numbers are low, such as with freshwater mussels. Other factors shared by several invertebrate SGCN groups that limit or impact populations include trampling/direct impacts, limited localized populations, and the requirement of specialized habitats.

**Research & Monitoring Needs and Conservation Strategies**

The Invertebrate Team identified priority research and monitoring projects to improve our ability to conserve Vermont's invertebrate SGCN. The Team also developed conservation strategies to address problems impacting each SGCN. Those used most frequently and those best applied to multiple invertebrate SGCN include:

**Research & Monitoring Needs**

1. Define particular habitat requirements of SGCN within Vermont, utilizing current knowledge of researchers and field investigations.
2. Determine important life history characteristics when such information is lacking for particular SCGN.

3. Obtain baseline SGCN distributional and abundance data by conducting surveys throughout the state.

4. Conduct inventories to detect and gather information on new SGCN populations.

5. Assess potential and existing impacts of problems on SGCN populations and their habitats.

6. Monitor trends in SGCN population size and structure, and in habitat.

7. Monitor current and potential threats to SCGN species.

Conservation Strategies

1. Conserve high priority SGCN sites through acquisition, easements, technical assistance, and other cooperative means.

2. Protect and restore aquatic habitats on which SGCN are dependent through pollution abatement, riparian buffers (ANR 2005), flow regulation, easements, and other means.

3. Work with foresters to avoid impacts to SGCN populations and habitats during forest management activities.

4. Work with biologists to minimize impacts to SGCN invertebrate populations and habitats during and following management activities for sport fish and game wildlife.

5. Participate in existing regulatory processes (e.g., Act 250, stream alteration permits) to protect and restore critical habitats.

Conclusion

The work to conserve our invertebrate SGCN has already begun. A Butterfly Atlas project was begun in 2002 to assess the distribution and abundance of butterfly species throughout Vermont. Coordinated by the Vermont Institute of Natural Science and funded by SWG, this initiative trains and utilizes volunteers to gather the data. The Vermont Fish & Wildlife Department has been active for many years investigating the distribution and population trends of several rare, threatened, and endangered invertebrates, including the cobblestone tiger beetle, brook floater, elktoe, and dwarf wedgemussel. Cooperation among several state and federal agencies, UVM, and The Nature Conservancy resulted in the Lake Champlain Native Mussel Working Group, which is dedicated to conserving native mussel populations within the Champlain Basin in both Vermont and New York. This group has been active in monitoring populations in Champlain tributaries and addressing threats to populations, such as the zebra mussel. All these efforts provide a good base from which Action Plan can help us launch new initiatives directed at invertebrate conservation.

See Appendix A for full reports on Invertebrate Groups of Greatest Conservation Need.

Team Charge
The Mammal Team was charged with identifying mammals of greatest conservation need (SGCN), describing the distribution and habitat usage for each SGCN; evaluating problems impacting SGCN and their habitat; identifying priority research needs to improve our ability to conserve these species; and, developing conservation strategies to address priority problems. Details of Species Team and other Action Plan team and committee charges can be found in Appendix D of this document.

Introduction
Sixty-one mammal species presently exist in Vermont or were here just prior to European settlement. Several of these species are now believed to be extirpated (elk, wolverine, wolf, mountain lion, caribou).

Although many of Vermont’s mammals are extremely adaptable and resilient (raccoon, red fox, skunk), others are sensitive to habitat loss and fragmentation (Indiana bat, bobcat, rock shrew), global warming (lynx, marten), competition (New England cottontail), and pollution (otter, mink, bats).

Some of the mammals listed as Species of Greatest Conservation Need (SGCN) presently appear to be secure but could be at risk in the next 20-30 years due to loss of critical habitats or population declines due to other environmental threats (black bear, otter, mink, little brown myotis, big brown bat). A number of species are facing immediate threats (New England cottontail, Indiana bat, marten, and lynx) and without attention could exist only as memories on the Vermont landscape. Others are listed primarily because little is known about the status and/or distribution of their populations in Vermont (hoary bat, shrews, gray fox, etc.). The Mammal Team interpreted the criteria for listing fairly broadly in hopes of preventing the decline of species that are presently secure. Funding sources for conservation may vary from federal aid to outside grants to the State Wildlife Grants program (reserved for species at greatest risk).
Selecting Mammal Species of Greatest Conservation Need

Of the sixty-one mammal species native to Vermont, the Mammal Team opted to list 23 as species of greatest conservation need and designate 3 (deer, moose, beaver) as species with ecological and/or social significance/influence.

The designation process included the completion of a matrix that identified distribution, population status, ranking, threats, and habitat/natural community requirements. Based on the results of the matrix, the Team prioritized the 61 species into high, medium, and low categories. Those species that were the most vulnerable (faced with immediate threats to survival or showing a significant population decline) were ranked as high. In addition, species that were extirpated locally but still existed regionally were included on the high list. Sixteen species were designated as having high conservation priority:

Seventeen additional species were ranked as medium. The Team was influenced by the legislative intent of “keeping common species common” so some of the species in the medium category were those that might be well-distributed and even locally abundant at the present time, but that Team members felt were at risk in the next 20-30 years due to the increasing potential for mortality or habitat loss/fragmentation. Mammals may have been included in the medium category either because little was known about their population status, distribution, and/or trends in Vermont or they have been considered extirpated in the region. Medium conservation priority species include:

Big brown bat, black bear, bobcat, gray fox, hairy-tailed mole, little brown bat, long-tailed weasel, masked shrew, mink, muskrat, northern flying squirrel, northern long-eared bat, river otter, smokey shrew, southern flying squirrel, mountain lion, and wolf.

Three species (beaver, moose, and white-tailed deer) were relegated to a special category due to the fact that they have significant ecological and/or social influence. Beaver are a keystone species that provides habitat for many other wildlife species. Loss of beaver and beaver-created wetlands in the 1600s through the 1700s probably resulted in the decline of otter, moose, a variety of invertebrates, brook trout, and associated songbirds. The reintroduction and subsequent trap and transfer program funded by hunters and trappers and implemented by the Fish & Wildlife Department in the 1920s through the 1950s, resulted in the re-establishment of beaver in Vermont. Since then, otter populations have recovered and moose, once extirpated, now exist through the State. Maintaining beaver-created wetlands has become more challenging as human activities expand into and around wetland habitats thus increasing the potential for beaver-human conflicts.

Deer and moose are species valued by many Vermonters. They can also have a significant ecological effect on the landscape. Populations of deer and moose that exceed carrying capacity
have a huge impact on regenerating forests and the herbaceous understory and can pose serious public safety threats. Presently, all three species are carefully managed and regulated by the Vermont Fish & Wildlife Department. By listing these species in a special category, the Team did not necessarily intend for State Wildlife Grant funds be directed towards them, but to simply highlight the importance of these species to the people and systems of Vermont.

Full reports on each Species of Greatest Conservation Need are in Appendix A of this document. The following is a summary of those reports.

**Habitat Needs**
The habitat needs of the mammals listed as SGCN, varies widely by species. In general, however, maintaining healthy populations of Vermont’s native mammals requires the conservation of critical habitats and the connective corridors that provide linkages between food, cover, and refugia habitats. In some cases, it also means conserving large blocks of contiguous forestland with corridors (including riparian buffers) to provide a network of large interconnected habitat blocks suitable for wide-ranging species such as lynx, bobcat, and black bear. Several researchers have recommended the establishment of an international effort to identify and protect biotic corridors for both the protection of biological diversity, as well as, to facilitate the movements of a variety of mammal and bird species across state and federal boundaries (Wydevan, 1998). This would require a cooperative effort between various local, state, and international governments as well as non-governmental organizations.

**Discussion of Problems**
The problems identified most frequently as threats to SGCN mammals were: Conversion of Habitat (24), Habitat Alteration (19), Pollution (16), and Loss of Prey Base (14). See Appendix A for full reports on each SGCN.

We do not understand all the ramifications, but the pattern seen elsewhere in the US and the world is that increased human population density, higher consumption of land and other resources, and lack of awareness of the impacts to other species can lead to devastating losses of native biota (TWS 2004). Vermont is not immune from these sorts of impacts and our landscape is continuing to be developed (DeVillars 1999). For example, Vermont lost an average of 6,500 acres of wildlife habitat is lost per year to development (Austin, pers.com). Habitat alteration and loss is a near universal challenge to many native mammal SGCN.

Pollution was also identified as a potential threat to species like mink and otter. Because they are at the top of the food chain, industrial pollutants, and heavy metals (PCBs, mercury, DDT) can build up in their bodies (Novak, 1987). Although the ramifications are not clear, it is likely that the biomagnification of these toxins negatively affects reproduction and survival. Bats are also extremely susceptible to pesticides and other environmental poisons because they store some lipophilic pesticides in brown adipose fat tissue. These stores are released as bats use their fat reserves during hibernation. Bats can, therefore, be exposed to both chronic and acute
poisoning, which can result in death. In addition, broad spectrum insecticides can deplete insect diversity and limit the food sources available for bats (loss of prey base).

Other threats that may influence the future of SGCN are global climate change, habitat fragmentation, competition, disease, impacts of roads and trails, invasion by exotic species, and trampling or direct impacts. Perhaps the biggest challenge for some species like bats, wolf, and mountain lion is the public’s understanding of the conservation of these species. According to the North American Bat Conservation Partnership Strategic Plan, “Throughout North America, sensational and inaccurate presentation of public health issues involving bats has created an exaggerated fear of these ecologically important species. The resulting unwarranted public perception presents an especially serious threat to bat survival. Although general public awareness of the values of bats has increased over the past two decades, ignorance remains an important impediment to bat conservation. Medical professionals, government agencies, private industry, and educators often lack materials necessary to educate the public about how to safely share their communities with bats” (http://www.batcon.org/nabcp/newsite/index.html).

Work done in other states on wolf recovery and management highlight the same issues. The number one strategy in the Michigan gray wolf recovery and management plan states “Public support is vital for the long-term survival of wolves in Michigan. Information and education efforts designed to exchange information with Michigan residents are essential and need to receive a high priority.” (Cool, 1997) It is clear that for some species recovery efforts must begin with a public outreach and education effort. To attempt recovery efforts without the support of the public is likely dooming them to failure.

Research and Monitoring Needs and Conservation Strategies
The Mammal Team developed research, monitoring, and conservation strategies for each individual SGCN species. Below is a compilation of the strategies that arose most frequently:

**Research and Monitoring**
1. Determine the distribution and relative abundance of populations in Vermont.
2. Determine critical habitat needs and connectivity requirements.
3. Identify and evaluate problems.
4. Determine life history requirements.

**Conservation Strategies**
1. Develop outreach and education programs that promote the conservation of SGCN and the habitats that they depend on, and increase awareness of the importance of maintaining or restoring these species.
2. Identify the habitat requirements of SGCN and develop strategies for conservation and protection through fee simple purchase, easements, management guidelines, and cooperative agreements with user groups and landowners, etc. (i.e. bat hibernacula and maternity roost trees, bobcat denning sites, reverting field habitat for New England cottontail, bear-scarred beech stands, connective corridors, etc.).
3. Initiate an international effort to maintain large blocks of undeveloped forests linked together by habitat corridors in order to provide a network of interconnected habitats throughout northeastern New England and southeastern Canada.

4. Maintain riparian buffers along streams (see ANR 2005).

5. Maintain and restore habitat connectivity and minimize fragmentation of forest blocks. Identify and prioritize wildlife road crossing locations. Work with the Agency of Transportation and adjacent landowners to reduce wildlife mortality and increase the potential for movement from one side of the road to the other.

6. Work to eliminate pollution that causes acid rain, the deposition of heavy metals, and global climate change.

7. Continue to work cooperatively with landowners, towns, and communities to protect critical habitats and maintain connectivity. Provide Conserving Vermont's Natural Heritage to municipal and regional planners (Austin et.al. 2004)

8. Participate in existing regulatory processes (e.g., Act 250, stream alteration permits) to protect and restore critical habitats.

Vermont is at a crossroad. Due primarily to conscious choices made by her citizens in the last 100 years (restoration of deer, beaver, turkey, fisher populations, enactment of Act 250 legislation and wetland regulations, etc.), as well as, economic forces that essentially allowed the state to bypass the Industrial Revolution (Bryan, pers com), Vermont has remained predominantly rural throughout the 20th century. Many mammal species, therefore, are at population levels that are likely higher than they were prior to European settlement (fisher, red fox, white-tailed deer, raccoon, bobcat). Today, however, with Vermont's population growing, development pressures increasing and increased roads and traffic the potential for significant habitat destruction in the next ten years is high. In addition, global climate change is already influencing the potential residency of some native mammal populations in Vermont (Royar, pers com). The decisions made by Vermonters today will chart the course for the future and influence the long-term viability of our native wildlife populations.

See Appendix A for full reports on each mammal Species of Greatest Conservation Need.

Conserving Vermont's Reptiles & Amphibians

Reptile & Amphibian Team
Steve Parren, Vermont Fish & Wildlife Dept (team leader)
Jim Andrews, Middlebury College
Steve Faccio, Vermont Institute of Natural Science
Chris Slesar, Vermont Agency of Transportation

Team Charge
The Reptile and Amphibian Team was charged with identifying Species of Greatest Conservation Need (SGCN); describing the distribution and habitat usage for each SGCN; evaluating problems impacting SGCN and their habitat; identifying priority research needs to improve our ability to conserve these species; and, developing conservation strategies to address priority problems. Details of Species Team and other Action Plan team and committee charges can be found in Appendix D of this document.

Introduction
For much of the year Vermont's 40 species of amphibians and reptiles, collectively known as herps or herptiles (from the Greek *Herpeton*), are secretive creatures shunning the fuss made over our more charismatic mega-fauna. But stand beside a Vermont wetland, pond or vernal pool on an early spring evening and the cacophony of calls from wood frogs, spring peepers, chorus frogs, and others and these enigmatic micro-fauna will make themselves noticed.

Vermont's reptiles and amphibians certainly deserve notice. As if their penchant for feasting on black flies, mosquitoes, garden slugs, rodents and other pests isn't reason enough to conserve them (some frogs are reported to eat as many as 3,000 insects a year), many also play critical roles in ecosystems, and serve as excellent indicators of the health of natural systems due to their sensitivity to toxic chemicals and habitat change.

Amphibians and reptiles face many conservation challenges in today's world, be it crossing high-traffic roads or the loss of habitat and connections between habitat patches. It could be argued that all 21 amphibians and 19 reptiles known to be extant in Vermont deserve Species of Greatest Conservation Need (SGCN) designation. The Action Plan Reptile and Amphibian Team took a conservative approach to selecting SGCN in order to highlight those species thought to be most in need of conservation assistance so that scarce resources can be directed toward their conservation.

Selecting Amphibian & Reptile SGCN
Selection criteria included knowledge about current listing as endangered and threatened, population declines, rarity, vulnerability of habitat, life history traits, vulnerability to collection or take, other impacts from humans, and dispersal capability. Each species was examined across all criteria and the four-person team developed a high, medium, and low conservation need ranking to attempt to separate species with greater need from those that may be more secure, at least in the short term (see Chapter 3: "Developing Vermont's Action Plan," for details on selection criteria and process). We created a numerical ranking
that assisted our assignment to high, medium, and low priority categories. This approach resulted in 12 species of high conservation need and seven of medium conservation need:

**High Conservation Need:** common mudpuppy, Jefferson salamander (and hybrids), Fowler’s toad, western chorus frog-E, eastern racer-T, eastern ratsnake-T, eastern ribbonsnake, timber rattlesnake-E, five-lined skink-E, spiny softshell turtle-T, spotted turtle-E and wood turtle (see Appendix I for definitions of the codes used here).

**Medium Conservation Need:** DeKay’s brownsnake, smooth greensnake, northern watersnake, common musk turtle, four-toed salamander, blue-spotted salamander, spotted salamander.

Though some of Vermont's SGCN are at the periphery of their range (e.g., western chorus frog, common mudpuppy, fowlers toad, and mink frog), a finding that challenges conventional wisdom is that species populations have been documented to be more at risk of loss at the core of their range than at the periphery (Channel & Lomolino 2000, Lomolino 1995). This argues for us giving serious consideration to SGCN that may be peripheral in Vermont.

Full reports on each Species of Greatest Conservation Need are in Appendix A of this document. The following is a summary of those reports.

**Habitat Needs**

Since many reptiles and amphibians use a variety of habitats annually and over the course of their lives, maintaining healthy populations entails maintaining connectivity between habitats. Connectivity also enables individuals to find alternative cover, food sources, breeding, or over-wintering sites when natural disasters occur. Furthermore, connectivity between populations ensures vital genetic exchange and allows for the re-colonization of areas where populations have been eliminated due to drought, winterkill, disease, or anthropogenic forces. This can only occur if the landscape is permeable to these animals—that is, development proceeds in a way that allows amphibians and reptiles to move freely across the landscape. To conserve our native amphibians and reptiles, especially those considered SGCN, it will be essential to maintain a network of interconnected sites where natural processes are allowed to occur.

**Discussion of Problems**

The problems identified most frequently as problems Vermont's reptile and amphibian populations are all closely related: trampling and direct impacts (all 19 SGCN), the impact of roads and trails (13), habitat fragmentation (17), habitat alteration (17), and habitat conversion (14). See appendix D for full reports on each SGCN.

We do not understand all the ramifications, but the pattern seen elsewhere in the US and the world is that increased human population density, higher consumption of land and other resources, and lack of awareness of the impacts to other species can lead to devastating losses of native biota (TWS 2004). Vermont is not immune from these sorts of impacts and our landscape is continuing to be developed (DeVillars 1999). Habitat alteration and loss is a near universal challenge to native amphibians and reptiles.
Crossing roads is a real problem for both amphibians and reptiles in Vermont. Vernal migrations of salamanders and frogs to breeding pools result in many dead and wounded animals when a busy road must be crossed. At some sites in Vermont, thousands of amphibians are killed during a single night, which may overwhelm the reproductive capacity to sustain the populations and, according to the Vermont Agency of Transportation, constitutes a public safety issue (C. Slesar, VTrans, pers comm). Female turtles seeking nest sites are more at risk of being killed on roads than more sedentary males, resulting in a sex bias in some populations and raises questions about population persistence (Sheen & Gibbs. 2004, Marchand & Litvaitis 2004). The still abundant, but believed to be declining, wood turtle often encounters roads in Vermont during its annual movements along riparian corridors. Snakes emerging from hibernation often bask on warm pavement, increasing their risk of being struck by vehicles.

Other factors that may negatively impact amphibians and reptiles now and in the foreseeable future include pollution, changes in hydrology, sedimentation, and global changes such as temperature and ozone depletion as well as disease and collection. A variety of frog malformations were documented in Vermont in recent years, and parasitic trematodes (flatworms), as well as agricultural chemicals, were implicated as causative agents (DEC 2004). And, while our long winter buffers us from some diseases and exotic invasions, such risks do exist. Botulism killed many mudpuppies in the Great Lakes only a few years ago. Red leg disease, which is caused by the parasite *Aeromonas hydrophilia*, has been documented in Vermont. Finally, some species, particularly turtles, may have too narrow a reproduction margin for exploitation as food or as pets.

**Research & Monitoring Needs and Conservation Strategies**

The Reptile and Amphibian Team identified priority research and monitoring projects to improve our ability to conserve Vermont's reptile and amphibian Species of Greatest Conservation Need. The Team also developed conservation strategies to address problems impacting each SGCN. Those used most frequently include:

**Research & Monitoring Needs**

1. Better determine habitat needs, identify significant breeding sites, vernal pools and habitat connections.
2. Better determine the distribution and relative abundance of populations in Vermont.

**Conservation Strategies**

1. Help people better value reptiles and amphibians and to understand the essential needs of all life stages, especially upland habitat in proximity to breeding pools.
2. Encourage reports of road-killed specimens, road crossings, and road basking areas to VFWD, VTrans, and the Vermont Reptile and Amphibian Atlas Project. Develop safer crossings at significant sites when roads are being upgraded.
3. Maintain habitat through appropriate management, direct habitat disturbance and site roadways away from sensitive sites such as breeding pools.

4. Continue to work cooperatively with landowners, habitat management agencies, towns and communities to protect habitat and maintain connectivity. Develop management guidelines for owners and managers of appropriate habitat.

5. Conserve known critical habitat through fee simple purchase, development rights or easements, management agreements and education of private landowners and managers.

6. If loss of important sites is likely due to development, consider creating or enhancing other pools that might allow some adults to transfer to the new site if they encounter it or develop a new breeding population from dispersal of colonizers.

7. Protect turtle nests and adults by predator trapping.

8. Work with biologists to minimize impacts to SGCN populations and habitats during and following management activities for sport fish and game wildlife.

9. Participate in existing regulatory processes (e.g., Act 250, stream alteration permits) to protect and restore critical habitats.

Vermont's Reptiles and amphibians are fortunate for a number of reasons. We have a much less developed landscape than many states. For example, even the eastern newt, a very abundant species in Vermont, is declining in Rhode Island due to development and roads (C.J. Raithel RI Dept of Environmental Management pers comm). We have an engaged Scientific Advisory Group on Reptiles and Amphibians that provides advice to the Vermont Endangered Species Committee. We also have a well developed Reptile and Amphibian Atlas Project (http://cat.middlebury.edu/herpatlas/) that mostly through volunteer efforts has collected, and continues to collect valuable information on the distribution of reptile and amphibian species in Vermont and raises awareness of conservation need in Vermont. Some groups in Vermont sponsor ‘salamander nights’ helping small amphibians cross roads safely and raise awareness about the impacts of traffic. The Vermont Fish and Wildlife Department continues to work on conservation projects that benefit reptiles and amphibians, including species listed here as SGCN, and we are working with other agencies including the Vermont Transportation Agency. More needs to be done, but with the foundation we already have in place, and the awareness and strengthening of partnerships promoted by Action Plan, we expect more conservation actions in our shared future.

See Appendix A for full reports on each reptile and amphibian Species of Greatest Conservation Need.

SGCN Conservation at Multiple Scales

Vermont's list of Species of Greatest Conservation Need (SGCN) comprises 144 vertebrate species (including chestnut sided-warbler, lake sturgeon, and spotted salamanders) as well as 192 invertebrate species (including tawny emperor butterflies, cobblestone tiger beetles, and giant floater mussels). Developing individual conservation plans for each SGCN would have been exhausting and impractical. Moreover, attempts to implement the more than 300 plans would be impossible due to insufficient resources and the high overall cost, resulting from the inefficiency of implementing many uncoordinated plans (not to mention problems reminiscent of the Keystone Cops stemming from the hundreds of biologists in the field bumping into each other).

Fortunately an easier, cheaper, and more efficient approach to addressing the needs of our Species of Greatest Conservation Need exists. That method consists of designing and implementing conservation efforts at multiple scales. For example, wildlife managers have been creating edge habitat for decades (Smith 1980) where, for example, an early successional stage of forest borders later successional forest. They do this because research shows that this improves conditions for deer, rabbit, turkey, ruffed grouse and several other species. In this example management actions were targeted at the habitat level.

Similarly, research in the 1960's and 1970's indicated that pesticides such as DDT so weakened the eggs of loon, osprey, peregrine falcons and many other birds of prey that eggs were collapsing under the weight of expectant parents. Not only did this add to nationwide population crashes, it also impeded restoration efforts because the pesticides remained in the birds for years. Action taken at the state and federal level—the regulation of pesticides—eventually helped these species and loon, osprey, peregrine falcon were finally removed from the Vermont's endangered species list in April of 2005.

Following this approach, we began at the species level by assessing SGCN individually. Then SGCN were organized by taxonomic group and by habitat usage with habitats grouped by vegetation type. This resulted in conservation strategies at five levels (table 4-1). Some species will always require specific conservation attention, such as those that are very rare, those that are declining across their range, those that aggregate for breeding, and those that require large home ranges. Their needs are addressed at the Species Level. Other species' needs can be met by the long-term conservation of high quality habitats and communities used by these species (the Community Level). Still other species will require conservation at the scale of wildlife travel corridors and large forest blocks (the Landscape Level).

Selection of Classification Systems

Though great strides have been made in developing vegetation classification systems that function at the site, landscape, region and national scales (Barnes 1979, Allen and Start 1982, Forman and Godron 1986, Cleland et. al 1997, Grossman et. al 1998) they are incomplete. In particular, no system satisfactorily integrates aquatic and terrestrial communities and cultural habitats¹ used by wildlife. The efforts of every

¹ Cultural habitats are communities and sites that are either created and/or maintained by human activities or are modified by human influence to such a degree that the physical condition is substantially different from what existed prior to human influence (adapted from Reschke 1990)
state, however, in development of their Action Plan greatly improve our prospects and plans are underway for coordination and information sharing once states' Action Plan reports are approved (IAFWA 2005).

In lieu of a unified habitat classification system, Vermont's Action Plan technical teams utilized the best features of five peer-reviewed vegetation classification systems that can be crosswalked with those used in other states to support broader scale conservation efforts—regionally, nationally, and internationally. Forest Cover Types (Eyre 1980) and U.S Forest Service Forest Inventory & Analysis Types (USDA 2003) were used for early successional stage forests. Natural Communities (Thompson and Sorenson 2000) were the basis most terrestrial vegetation. "A Classification of the Aquatic Communities of Vermont" by Langdon et. al. (1998) was adapted for aquatic community designations and cultural habitats were adapted from Reschke (1990). Landscape scale communities were adapted from Poiani et.al. (2000).

One hundred 120 aquatic and natural community types, cultural habitats and land cover types, capturing most of the habitat required by SGCN were selected from the five systems (table 4-2). Each was assigned to one of 22 categories. Because Lake Champlain and the Connecticut River harbor most of the fish diversity in Vermont, these two waterbodies were broken out from the taxonomy to provide for a more targeted assessment. Technical teams then developed assessment summaries for each that includes descriptions and general locations; current conditions; desired conditions based on the needs of associated SGCN; priority problems; conservation strategies to address problems (along with the identification of potential conservation partners and funding sources); and a listing of relevant plans and planning processes pertinent to a habitat type. (Appendix B)

In addition, three landscapes were selected (forest, riparian, and fluvial/stream) to address connectivity needs of many SGCN as well as the needs of wide-ranging SGCN. Assessment summaries were also completed for each landscape (see this chapter).

**Successional Stages, Species of Greatest Conservation Need & the Action Plan**

Plant succession produces cumulative change in the types of plant species occupying a given area through time. It is complicated by factors such as disturbance (large and small), local conditions, seed banks and soil legacies (Oliver 1981). A highly simplified timeline begins when land is cleared. Pioneer species typically return first followed by other species generally better adapted to the new and changing conditions created by the previous suite of species. Given sufficient time and appropriate conditions the area moves roughly through early, middle, and late successional stages—often referred to as mature or old growth. A disturbance, if sufficiently large, can re-set the clock anytime and succession begins again. The best known examples are forest succession but it occurs in virtually all vegetated areas. For example, lichen communities on granite mountaintops experience successional changes (Wessels 2002).

Succession can significantly impact habitat for Species of Greatest Conservation Need and other wildlife as in the edge habitat example noted earlier. Generally as succession moves from early to late stages some wildlife will lose out (e.g., spruce grouse, woodcock, cottontail rabbit) and others will benefit (e.g., marten, northern goshawk). Others still prefer a mix of successional stages in appropriate configurations (e.g., black bear, lynx).

Over the past two centuries the mix of successional stages available to Vermont's wildlife has changed dramatically in both distribution and abundance. Though precise estimates (current and historic) are unavailable, prior to 1800 a significant percentage of Vermont's forests were in late-successional stages (>150-300 years and older). One-hundred years later early-successional stages (1-15 years) dominated the state and today mid-successional forests (60-100 years) are most abundant. Wildlife populations have responded in turn. Vermont's SGCN list contains relatively few species requiring mid-successional forests and more that thrive in early and late-successional representations.
Because the loss of late-successional forests in the eastern US occurred prior to the advent of modern wildlife biology and the current scarcity of later-successional stages (particularly northern hardwood forest types) our understanding how wildlife utilized these stages is not as advanced as our knowledge of wildlife in early successional stages. Historic records and research in late-successional areas elsewhere indicate that the distribution and abundance of some wildlife species was much greater when late-successional forests were in greater abundance—even if these species can survive without them. Given the lack of this condition on the landscape it is advisable to increase its availability to wildlife.

The habitat, community and landscape summaries that follow here and in Appendix B address habitat the needs of Species of Greatest Conservation Need that use that vegetation type in one or more successional stages. Conservation strategies address the particular successional stage needs well those species that prefer a mosaic of successional stages.

**Table 4-2: Landscape, Community, Habitat & Cover Type Categories**

* Categories marked with an asterisk “*” are considered major categories for the purposes of organizing this report (24 in all). Conservation summaries were developed addressing characteristics and location, current and desired condition, SGCN using this habitat category, priority problems impacting this category, conservation strategies to address the problems and a list of other plans and planning entities with significant interest in this area.

  - Alder swamp
  - Alluvial shrub swamp
  - Sweet gale shoreline swamp
  - Buttonbush swamp

**Forested Wetlands**
- *Floodplain Forests*
  - Silver maple-ostrich fern riverine floodplain forest
  - Lakeside floodplain forest
  - Silver maple-sensitive fern riverine floodplain forest
  - Sugar maple-ostrich fern riverine floodplain forest
- *Hardwood Swamps*
  - Red maple-black ash swamp
  - Red maple-northern white cedar swamp
  - Calcareous red maple-tamarack swamp
  - Red or silver maple-green ash swamp
  - Red maple-black gum swamp
  - Red maple-white pine-huckleberry swamp
- *Softwood Swamps*
  - Northern white cedar swamp
  - Spruce-fir-tamarack swamp
  - Black spruce swamp
  - Hemlock swamp
- *Seeps & Vernal Pools*
  - Vernal pool
  - Seep

**Open Upland Communities**
- *Upland shores*
  - Riverside outcrop
  - Lake sand beach
  - Lake shale or cobble beach
  - Erosional river bluff
  - Sand dune
- *Outcrops & Upland Meadows*
  - Alpine meadow
  - Boreal outcrop
  - Serpentine outcrop
  - Temperate acidic outcrop
  - Temperate calcareous outcrop
- *Cliffs & Talus*
  - Boreal acidic cliff
  - Boreal calcareous cliff
  - Temperate acidic cliff
  - Temperate calcareous cliff
  - Open talus

**Upland Forests & Woodlands**
- *Spruce-Fir Northern Hardwood Forest*
  - (included with landscape forest summary)
  - Subalpine krummholz
  - Montane spruce-fir forest
  - Lowland spruce-fir forest
  - Montane yellow birch-red spruce forest
  - Boreal talus woodland
  - Cold-air talus woodland
  - Red spruce-northern hardwood forest
- *Northern Hardwood Forest*
  - (included with landscape forest summary)
  - Northern hardwood forest
  - Rich northern hardwood forest
  - White pine-northern hardwood forest
  - Mesic red oak-northern hardwood forest
  - Hemlock forest
  - Hemlock-northern hardwood forest
  - Northern hardwood talus woodland
- *Oak-Pine-Northern Hardwood Forest (included with landscape forest summary)*
  - Limestone bluff cedar-pine forest
  - Mesic maple-ash-hickory-oak forest
  - Valley clayplain forest
  - White pine-red oak-black oak forest
  - Dry oak forest
  - Pine-oak-heath sandplain forest
  - Dry oak-hickory-hophornbeam forest
  - Red cedar woodland
  - Red pine forest or woodland
  - Pitch pine-oak-heath rocky summit
  - Dry oak woodland
  - Transition hardwood talus woodland

Chapter 4: Conserving Vermont's Wildlife Resources Conservation at Multiple Scales Vermont's Wildlife Action Plan 11/22/2005
Landscape Forest Summary

Vermont’s three primary landscape scale forests – Northern Hardwood, Spruce-Fir-Northern Hardwood, and Oak-Pine-Northern Hardwood – form the foundation of the state’s forested habitat that supports many of Vermont’s SGCN. These landscapes function at two different levels. First, in sum, these three forests, if maintained in large, interconnected forest blocks, meet the large scale habitat needs of Vermont’s widest ranging wildlife species that move throughout the landscape. Secondly, each of the three large forests hosts numerous SGCN that may require one or more of the natural community types associated with that respective large forest. In general, habitat requirements, problems, and conservation strategies should be assessed and developed at both levels. However, in many cases, the landscape scale forest provides most of the habitat needs for many of the SGCN associated with one of the habitats or natural community types.

Characteristics and Location
Landscape Level Forest provides both the area and habitat needed by Vermont’s wide-ranging wildlife species. These species use the full mosaic of diverse habitats associated with Vermont’s upland forestland frequently crossing habitat boundaries. The conservation and management of Vermont’s landscape level forests for wide-ranging wildlife also provides the essential habitat for all SGCN that depend on the natural communities associated with those habitats.

Habitats associated with the landscape level forest

Northern Hardwood Forest: The Northern Hardwood Forest is best developed at Vermont’s middle elevations and is widespread in the state. Beech, sugar maple, and yellow birch are the prominent tree species, but hemlock, red oak, red maple, white ash, basswood, and white pine can be common as well, with some scattered red spruce. These are the dominant communities in nearly all biophysical regions, excepting for the highest elevations of the Green Mountains and the lowest elevations in the Champlain Valley.

Spruce-Fir-Northern Hardwood Forest: The Spruce-Fir-Northern Hardwood Forest is found in the coldest regions of the state. Red spruce and balsam fir are the most abundant trees at higher elevations and in low, cold, moist areas. Other conifers include white spruce, black spruce, northern white cedar, and tamarack. Warmer and better drained sites have significant amounts of hardwood, including yellow birch, sugar maple, and beech with paper birch at mid-elevations. Conifer and mixed forests of this habitat blanket Vermont’s highest peaks above 2,500 feet.

Oak-Pine-Northern Hardwood Forest: The Oak-Northern Hardwood Forest is best developed in the warmer regions of Vermont—the Southern Vermont Piedmont, Champlain Valley, and the lower elevations in the Taconic Mountains. These forest communities generally occur as large patches or locally as small patches within Northern Hardwood Forests and on dry, south-facing slopes and ridgetops. In the Oak-Northern Hardwood Forest, hardwoods such as sugar maple, beech and yellow birch are common,
but warmer climate species such as red oak, shagbark hickory, and white oak can be present in significant numbers. White pine is a prominent part of this Forest.

Landscape Forest Condition

**Historical Perspective:** It has been estimated that 95% of Vermont was forested when Europeans first arrived in the early 1600s. The population of Native Americans in the Champlain Valley and Connecticut River valley in the early 1600s was only 8,000 and only a small amount of forestland was cleared for agriculture, primarily in the river valleys (Klyza and Trombulak 1999). Significant forest clearing began with the arrival of European settlers, however, primarily for lumber, fuelwood, potash, and agriculture. It has been roughly estimated that the percent of forest cover in Vermont was reduced to 82% by 1790, 47% by 1850, and reached a low of 37% by 1880, after which the area of forest began to increase as farms were abandoned (various sources in Klyza and Trombulak 1999). According to Harper (1918), by 1850 more than 60% of the land in New England had been cleared for agriculture.

The effect on Vermont's forests was not limited to clearing. Forests in the region that were not cleared were typically on steep slopes, stony ground, or poorly drained soils. Many of these were heavily harvested for timber and many were used as woodland pastures, with the result that virtually all of our forests have been altered by human activity (Whitney 1994). In general, our forests today are much younger than the presettlement forests. The composition of presettlement forests was also different from our present-day forests, as has been described in several studies of early land survey records that documented witness and boundary line trees (Siccama 1971, Cogbill 1998, Cogbill 2000, Cogbill et al. 2002). These studies indicate that beech was much more abundant in presettlement forests, whereas sugar maple and white pine were less abundant. Red spruce was more abundant in mid-elevation presettlement forests, whereas red maple, white birch, and poplars – species now associated with younger forests and human activity – were much less abundant in the presettlement forests (Cogbill 2000).

Prior to European settlement in the northeastern United States, natural disturbance (including wind, fire, and flooding) were the primary forces affecting the region's forests. In Vermont, wind has been the primary source of natural disturbance in upland forests, ranging from frequent local blowdowns of individual trees to infrequent hurricane events that can affect thousands of acres. A recent study, based on the review of many sources of information, provides figures on the expected percentage of the presettlement regional landscape occupied by different age classes (Lorimer and White 2003). For northern hardwood forest, the expected percentage occupied by uneven aged forest over 150 years ranges from 70 to 89 percent, depending on the assumptions and models used. In these forests, from 1.1 to 3.0 percent was occupied by early successional forests (1-15 year age class). For spruce-northern hardwood forest, the expected percentage occupied by uneven aged forest over 150 years ranges from 35 to 78 percent, depending on the assumptions and models used. In these forests, from 2.4 to 7.1 percent was occupied by early successional forests (1-15 year age class).

**Current Condition:** Vermont’s landscape level forest for wide-ranging wildlife species is influenced by two, diverging trends in the state’s forestland. First, Vermont is experiencing
increasing acreage of forest in the state. As of 1997, Vermont was estimated to be 78% forested; however, this varies greatly by biophysical region, ranging from 94% forested in the Southern Green Mountains to 40% in the Champlain Valley (Frieswyk and Widmann 2000). Second, however, Vermont’s blocks of contiguous forestland have become broken into smaller and smaller units as forests are converted to other land uses, primarily new housing and commercial development and new and/or upgraded roads. Again, the availability of large blocks of contiguous forestland varies by biophysical region with the Northeast Highlands and Green Mountains having the most contiguous forest and the Champlain Valley and Vermont Valley comprised of the smaller, fragmented forests.

The landscape level forest also varies greatly in the proportion of the forest in various successional stages. In general, early successional forest is available on 10% of the state’s forestland, ranging from 2.7% in the Taconic Mountains to over 19% in the Northern Vermont Piedmont (Frieswyk and Widmann 2000). The current availability of late successional stage habitat is nearly non-existent in the state, although trends lean toward an increasing availability of this habitat, particularly in the Southern Green Mountains.

In general, the highest forest elevations are more vulnerable to immediate impacts of both climate change and pollution. These areas also contain the more fragile soils. The lower elevation forests are more vulnerable to permanent conversion and to fragmentation of forest blocks.

**Desired Condition (SGCN Needs):** The habitat needs of wide ranging wildlife species is best met by maintaining large blocks of contiguous forest connected by linkages. Species such as black bear, marten, river otter, lynx, wolf, and others cross forest boundaries. Successful conservation and management of these wide ranging species therefore requires a landscape level approach, compounding the complexity of development and implementation of successful strategies. Management for early successional forest may enhance an area for some wide-ranging wildlife (e.g., black bear, lynx), while others may require that a large portion of their home range be managed for late successional forest stages (e.g., pine marten). Management schemes should therefore be designed at the landscape level in order to maintain blocks of intact, minimally roaded, forest while encouraging early successional harvests in areas that are already fragmented (Dan Harrison, pers. com. 2004). Paved roads, housing development, and other permanent conversions of forest are cumulatively detrimental to most wide-ranging wildlife.

Potential habitat for wide-ranging SGCN can be defined through the overlay of the marten habitat map (Carroll 2004), lynx habitat map (Carroll 2004), black bear habitat (Vermont Fish and Wildlife Department 1989), unfragmented forest block map (Feree 2004), contiguous forest block map (UVM spatial analysis lab 2005), and the maps describing potential wolf habitat (Harrison and Chapin 1998).

Several wide-ranging wildlife species will not persist or become re-established without linkages to other states and Canada. Therefore, regional connectivity (i.e., linkages to New York, New Hampshire, and Canada) must be maintained and statewide connectivity within Vermont be restored through the re-establishment of forest and linkages in the more fragmented biophysical regions. Linkages along riparian habitats will also provide connectivity for both semi-aquatic and upland species.
The total amount of forested area needed by wide-ranging SGCN varies greatly based on the home range requirements of a species, habitat quality, and the number of individuals needed to sustain the population. In general, some area sensitive birds may require a minimum forest block size of 7500 acres (Robbins et. al. 1989), bobcat populations of 250 breeding females require approximately 2000 square miles, and maintaining Vermont’s black bear population may require as much as 6000 square miles of habitat (Vermont Fish & Wildlife Black Bear Management Plan 199__). Some species are so wide-ranging that Vermont can meet only a portion of their population’s current or potential habitat needs (e.g., lynx, wolf, marten). In addition, maintaining viable populations of migrating songbirds and raptors may require conservation of wintering grounds in other parts of the country and world.

Northern Hardwood Forest Summary

Characteristics and Location
The Northern Hardwood Forest is best developed at Vermont's middle elevations and these are widespread in the state. Beech, sugar maple, and yellow birch are the predominant tree species, but hemlock, red oak, red maple, white ash, basswood, and white pine can be common as well, and red spruce makes an occasional appearance.

These are the dominant communities in nearly all biophysical regions, excepting the higher elevations of the Green Mountains and the warmer regions of the Champlain Valley, Taconic Mountains, and Southern Vermont Piedmont. Where the natural communities serve as landscape level habitat (i.e., matrix), they should be represented in large blocks of contiguous forest (1,000 acre to 20,000 acre blocks) of various successional stages, elevation, and soils.

The natural communities that comprise Northern Hardwood forest formation habitat are found in every biophysical region of the state.

Natural communities of the Northern Hardwood Forest:

**Northern Hardwood Forest:** A variable community, generally dominated by beech, sugar maple, and yellow birch. This community occurs as a landscape natural community type (i.e., matrix) throughout the state.

**Rich Northern Hardwood Forest:** High diversity hardwood forests of sugar maple, white ash, and basswood, with excellent productivity and high herb diversity. Maidenhair fern, blue cohosh and wood nettle are characteristic herbs. This community occurs as a landscape natural community type (i.e., matrix) in the Taconic Mountains.

**White Pine-Northern Hardwood Forest:** Areas where white pine is a significant canopy component of Northern Hardwood Forests, usually where soils are coarser and better drained.

**Mesic Red Oak-Northern Hardwood Forest:** Northern hardwood species and red oak co-dominate. Mostly on south-facing slopes in the northern parts of Vermont.

**Hemlock Forest:** Dominated by hemlock, often on shallow soils.

**Hemlock-Northern Hardwood Forest:** Mixed forest of hemlock and northern hardwoods. This community occurs as a landscape natural community type (i.e., matrix) in the Southern Vermont Piedmont and the Taconic Mountains.

**Northern Hardwood Talus Woodland:** Characteristic species are mountain, rock polypody, red berried elder, and Northern Hardwood species.

Northern Hardwood Forest Condition

Historical Perspective: Northern Hardwood Forests have dominated the Vermont landscape for at least the last 4,500 years, a period over which there was a gradual cooling of the climate. These past forests are believed to have fairly closely resembled the composition
of forests of today. Notable differences in the presettlement northern hardwood forests were the predominance of beech, making up over 40% of the trees (Siccama 1971) and the lower abundance of sugar maple. Although red spruce has decreased in abundance since presettlement times at mid-elevations, it has increased in abundance in valleys due to regeneration in old fields (Hamburg and Cogbill 1988). Similarly, white pine is now more abundant due to its regrowth in abandoned fields (Cogbill 2000). Presettlement forests also likely had much less red maple, white birch, and poplars than the forests of today, as these species are associated with younger forests (Cogbill 2000).

**Current Condition:** Vermont’s Northern Hardwood Habitat has become more widespread as farmland on the slopes and in the valleys has reverted to forest. However, human population growth and economic development result in forestland conversion and fragmentation that yield smaller blocks of contiguous Northern Hardwood. While much of the Northern Hardwood Forests has been cleared or logged at one time, current land management trends will likely yield less early successional habitat in the future.

**Desired Condition (SGCN Needs):** Northern Hardwood Forest should be represented in both large blocks of contiguous forestland that contribute to the full complement of landscape level habitat for wide-ranging species, as well as in the natural community types that serve specific SGCN associated with that type. The large, contiguous forest blocks of Northern Hardwood Forest should exist in 1,000 to 20,000 acre blocks of various successional stages, elevations, and soils and well represented within each biophysical region. Prey wildlife species supported by northern hardwoods are an important component to maintaining several of the wide-ranging wildlife. In addition, the value of hard mast as wildlife food (i.e., nuts and acorns) from northern hardwoods is important for many SGCN with stands of bear-scarred American beech being a classic example.
### Species of Greatest Conservation Need in Northern Hardwood Forest

#### High Priority
- Canada Warbler (Wilsonia canadensis)
- Jefferson Salamander (Ambystoma jeffersonianum)
- Fowler’s Toad (Bufo fowleri)
- Spotted Turtle (Clemmys guttata)
- Wood Turtle (Clemmys insculpata)
- Hardwood Forest Butterflies Group (Edwards’ hairstreak)
- Silver-haired Bat (Lasionycteris noctivigans)
- Eastern Red Bat (Lasiusus borealis)
- Hoary Bat (Lasiusus cinereus)
- Woodland Vole (Microtus pinetorum)
- Long-tailed or Rock Shrew (Sorex dispar)
- Pygmy Shrew (Sorex hoyi)
- Water Shrew (Sorex palustris)
- Southern Bog Lemming (Synaptomys cooperi)

#### Medium Priority
- Cooper’s Hawk (Accipiter cooperii)
- Long-eared Owl (Asio otus)
- Red-shouldered Hawk (Buteo lineatus)
- Veery (Catharus fuscescens)
- Chimney Swift (Chaetura pelagica)
- Black-billed Cuckoo (Coccyzus erythropthalmus)
- Black-throated Blue Warbler (Dendroica caerulescens)
- Wood Thrush (Hylocichla mustelina)
- American Woodcock (Scolopax minor)
- Chestnut-sided Warbler (Dendroica pensylvanica)
- Ruffed Grouse (Bonasa umbellus)
- Blue-spotted Salamander (Ambystoma laterale)
- Spotted Salamander (Ambystoma maculatum)
- Four-toed Salamander (Hemidactylium scutatum)
- Brown Snake (Storeria dekayi)
- Long-tailed Weasel (Mustela frenata)
- Hairy-tailed Mole (Parascalops breweri)
- Cinereus or Masked Shrew (Sorex cinereus)
- Smoky Shrew (Sorex fumeus)
- Common Gray Fox (Urocyon cinereoargenteus)
- Mink (Mustella vison)
- Black bear (Ursus americanus)

#### SGCN Note:
Plant SGCN not listed here: 59 species. The SGCN invertebrate group listed here contains numerous species. For more information about a specific Species of Greatest Conservation Need see that species' assessment summary in Appendix A.

Spruce-Fir-Northern Hardwood Forest Summary

Characteristics and location
These forests characterize our coldest regions. At higher elevations and in low cold, moist areas, red spruce and balsam fir may dominate the canopy. Warmer or better drained sites have significant amounts of hardwoods (yellow birch, sugar maple, and beech) along with softwoods in the canopy. Human or natural disturbance can also lead to temporary dominance by hardwood species.

These forests occur where growing seasons are short, summers are cool, and winters are harsh. The conifer-dominated forests blanket our highest peaks above 2,500 feet as well as occurring in cold lowland pockets within large areas of Northern Hardwood Forest. The mixed forests of red spruce and hardwoods are more widely distributed.

**Subalpine Krummholz**: Low, dense thickets of balsam fir and black spruce at high elevations. Generally shallow to bedrock.

**Montane Spruce-fir Forest**: Dominated by red spruce and balsam fir, with occasional heartleaf birch, paper birch, and yellow birch. Higher elevations generally above 2,500 feet.

**Lowland Spruce-Fir Forest**: Dominated by red spruce and balsam fir, with occasional white spruce, black spruce, paper birch, and yellow birch. Lowlands of Northeastern Highlands and cold valleys elsewhere.

**Montane Yellow Birch-Red Spruce Forest**: Mixed forest at high elevations (2,200-3,000 feet), dominated by yellow birch, and red spruce.

**Red Spruce-Northern Hardwood Forest**: Mixed forest of red spruce, yellow birch, sugar maple, beech, balsam fir, white ash, and other species, not associated with mountain slopes, generally below 2,400 feet elevation, sometimes up to 2,700 feet. A variable community.

**Boreal Talus Woodlands**: Rockfall slopes dominated by heart-leaved paper birch with occasional red spruce. Appalachian polypody, skunk currant, and mountain maple are often abundant.

**Cold-Air Talus Woodland**: Rare. Found where cold air drains at the bases of large talus areas. Characteristic plants are black spruce, abundant mosses and liverworts, foliose lichens, and Labrador tea.

Spruce-Fir-Northern Hardwood Forest Condition
**Historical Perspective**: In recent geologic time, forests dominated by spruce and fir became established in eastern North America only as recently as 8,000 years ago (Webb 1987). A warming trend, known as the hypsithermal interval, occurred from about 6,000 to 4,000 years ago, at which time spruce and fir dominated forests were greatly reduced in distribution. There has been a general expansion of spruce and fir since this time associated with a general cooling of climate (Klyza and Trombulak 1999).
Balsam fir has increased substantially when compared to presettlement forests, likely the result of its competitive advantage over spruce after heavy cutting (Whitney 1994). Red spruce has decreased in abundance at mid-elevation as a result of natural climate warming after the "little ice age" and forest harvesting, whereas it has increased in abundance in valley settings as a result of regeneration in old fields (Hamburg and Cogbill 1988).

**Current Condition:** Many of the natural communities within the spruce–fir–northern hardwood formation exist at high elevations and are often on shallow, acidic, infertile soils. They are, therefore, particularly susceptible to global climate change and acid rain. In addition, fragmentation through permanent conversion of forest blocks to roads, houses, ski trails etc. pose the most significant problems to this forest type and the species that depend on it.

**Desired Condition (SGCN Needs):** Many of the below listed SGCN depend upon large, contiguous, interconnected, forest blocks. Where they exist within a biophysical region, examples of large, intact blocks of appropriate natural communities should be conserved to ensure the long-term viability of the associated SGCN (i.e. Montane Spruce Fir: black poll warbler, olive-sided flycatcher, Bicknell's thrush, bay-breasted warbler; Lowland Spruce Fir: black-backed woodpecker, gray jay, bay-breasted warbler). Contiguous forest blocks will ideally exist in 1,000-20,000 acre blocks at various elevations and of various soil types. Conservation of these blocks should incorporate SCGN distribution and habitat needs.

**SGCN in Spruce-Fir Northern Hardwood Forest**

**High Priority**
- Bicknell's Thrush (Catharus bicknelli)
- Spruce Grouse (Falcipennis canadensis)
- Canada Warbler (Wilsonia canadensis)
- Jefferson Salamander (Ambystoma jeffersonianum)
- Wood Turtle (Clemmys insculpta)
- Tiger Beetles Group
- Eastern Red Bat (Lasiurus borealis)
- Hoary Bat (Lasiurus cinereus)
- Lynx (Lynx canadensis)
- American Marten (Martes americana)
- Rock Vole (Microtus chrotorrhinus)
- Woodland Vole (Microtus pinetorum)
- Long-tailed or Rock Shrew (Sorex dispar)
- Water Shrew (Sorex palustris)
- Northern bog lemming (Synaptomys borealis)
- Southern Bog Lemming (Synaptomys

**Medium Priority**
- Cooper's Hawk (Accipiter cooperii)
- Northern Goshawk (Accipiter gentilis)
- Long-eared Owl (Asio otus)
- Chimney Swift (Chaetura pelagica)
- Black-billed Cuckoo (Coccyzus erythropthalmus)
- Olive-sided Flycatcher (Contopus cooperi)
- Black-throated Blue Warbler (Dendroica caerulescens)
- Bay-breasted Warbler (Dendroica castanea)
- Blackpoll Warbler (Dendroica striata)
- Gray Jay (Perisoreus canadensis)
- Black-backed Woodpecker (Picoides arcticus)
- Blue-spotted Salamander (Ambystoma laterale)
- Spotted Salamander (Ambystoma maculatum)
- Wolf (Canis ?)
- Mountain Lion (Felis concolor)
- Long-tailed Weasel (Mustela frenata)
- Hairy-tailed Mole (Parascalops breweri)
- Cinereus or Masked Shrew (Sorex cinereus)
- Smoky Shrew (Sorex fumeus)
- Black Bear (Ursus americanus)
SGCN Note: Plant SGCN not listed here: 21 species. The SGCN invertebrate group listed here contains numerous species. Wolf and mountain lion utilize this spruce-fir northern hardwood forests but are addressed in the Landscape Forest Summary. For more information about a specific Species of Greatest Conservation Need see that species' assessment summary in Appendix A1-A5.

Oak-Pine-Northern Hardwood Forest Summary

Characteristics and Location
The Oak-Pine-Northern Hardwood Forest is best developed in the warmer regions of Vermont—the Southern Vermont Piedmont, Champlain Valley, and the lower elevations in the Taconic Mountains. Forest communities in this formation generally occur as large patches or locally as small patches within Northern Hardwood Forests and on dry, south-facing slopes and ridgetops. In the Oak-Northern Hardwood Forest Formation, hardwoods such as sugar maple, beech and yellow birch are common, but warmer climate species such as red oak, shagbark hickory, and white oak can be present in significant numbers. White pine is a prominent part of this formation.

The natural communities that comprise the Oak-Pine-Northern Hardwood forest type are diverse in their species composition, but all have species that occur in warmer climates, or on dryer sites such as south-facing rocky ridges.

Natural communities of the Oak-Pine-Northern Hardwood Forest:

**Red Pine Forest or Woodland:** Maintained by fire, these small areas are dominated by red pine, have very shallow soils, and have blueberries and huckleberries in the understory. They are widespread, and often surrounded by Northern Hardwood Forests.

**Pitch Pine-Oak-Heath Rocky Summit:** These are fire-adapted communities on dry, acidic ridgetops where red oak, white oak, pitch pine, scrub oak, and white pine are characteristic trees. Heath shrubs (blueberries and huckleberries) are abundant.

**Limestone Bluff Cedar-Pine Forest:** Northern white cedar dominates these areas of shallow soils over calcareous bedrock. Red pine, white pine, hemlock, and hardwoods are also present. Characteristic herbs are ebony sedge and rock polypody. This community has suffered high degree of loss from historic levels due to shoreline development.

**Red Cedar Woodland:** These are open glade-like communities on ledge crests, where red cedar is native and persistent, and grasses and sedges dominate the ground layer.

**Dry Oak Woodland:** These are very open areas with trees of low stature on dry, south facing hilltops. Grasses and Pennsylvania sedge are dominant on the forest floor.

**Dry Oak Forest:** These forests occur on rocky hilltops with very shallow, infertile soils. Red oak, chestnut oak and white oak can all be present; usually other tree species are absent. Heath shrubs dominate the understory.

**Dry Oak-Hickory-Hophornbeam Forest:** These forests occur on till-derived soils, but they are often found on hilltops and bedrock exposures are common. Soils are well drained, but are more fertile than in Dry Oak Forests. Red oak, sugar maple, hophornbeam, and shagbark hickory are variously dominant. Sometimes sugar maple is the dominant tree, sometimes it is oak and hickory. Pennsylvania sedge forms lawns.

**Mesic Maple-Ash-Hickory-Oak Forest:** Sugar maple, white ash, hickories and red and white oak are present in varying abundances. This community needs better documentation.
Valley Clayplain Forest: Found on the clay soils of the Champlain Valley, this forest is variously dominated by white oak, swamp white oak, bur oak, hemlock, red maple, and shagbark hickory. Soils are poorly drained. Clay plain forests in Vermont have declined by 87.9% since pre-European settlement (Lapin 2003).

White Pine-Red Oak-Black Oak Forest: These forests are found on coarse-textured soils. Red and black oak co-dominate along with white pine. Beech and hemlock are also common. Heath shrubs are common in the understory.

Pine-Oak-Heath Sandplain Forest: This is a rare community type, found on dry sandy soils in warmer areas. Characteristic species are white pine, pitch pine, black oak, and red oak with an understory dominated by heath shrubs. Due to high development pressure, only 5% of the original 15,000 acres of sandplain forest in Chittenden County remain (Engstrom 1991).

Transition Hardwood Talus Woodland: These talus woodlands are found in warmer areas, often on limestone but occasionally on slate, schist, granite, gneiss, or other rock. Some characteristic species are red oak, basswood, white ash, sweet birch, bitternut hickory, northern white cedar, hackberry, bulblet fern, and American yew.

Oak-Pine-Northern Hardwood Forest Condition

Historical Perspective: The natural communities that we recognize now are not static – they have changed dramatically over time as component species have migrated across the landscape in response to climatic change. The Oak-Pine-Northern Hardwood Forest Formation (and its characteristic species: pine, oak, and hickory) provides a good example of how species migrations are independent of each other. After the retreat of the glaciers to the north, pine became well established in the northeastern United States by about 12,000 years ago, while oak was not well established until about 8,000 years ago, and hickory arrived in New England 2,000 to 3,000 years after the first increase in oak populations (Jacobson et al. 1987; Prentice et al. 1991).

It is often thought that white pine dominated the presettlement landscape of Vermont, but evidence from early land surveys indicates that it had a variable and restricted distribution (Cogbill 2000). Pine was abundant only in scattered areas of the Champlain and Connecticut River valleys, and was generally uncommon elsewhere. White pine has more than doubled in frequency since presettlement times, apparently due to its establishment and growth in abandoned agricultural fields (Cogbill 2000).

Current Condition: Of the three landscape level forests in Vermont, the Oak-Pine-Northern Hardwood Forest has been the most altered by human activities. The primary reason may be that this forest type is most closely associated with the Champlain and Connecticut River Valleys – Vermont’s most populated and agricultural regions. The Oak-Pine-Northern Hardwood Formation occurs in the warmest region of the state that are generally the most desirable for settlement and agriculture. Human alteration of the landscape has most significantly altered some of the larger natural community types (i.e., Valley Clayplain Forest, Pine-Oak-Heath Sandplain Forest) of this forest. In fact, in the southern Champlain Valley 87.9% of the Clay Plain Forest has been lost or degraded (Lapin 2003), primarily as a result of conversion to agricultural uses. One of Vermont’s rarest and most threatened natural communities is the Pine-Oak-Heath Sandplain Forest of the northern Champlain Valley. As a consequence of its high value for residential development,
it has been estimated that only 5% of the original 15,000 acres of sandplain forest now remain in Chittenden County (Engstrom 1991). Many of the rarest SGCN are directly associated with these communities.

Many of the other natural communities of this forest are small in size and often isolated. Several are found along drier ridgetops that make them less vulnerable to forestland conversion. However, fire suppression over the past 200 years or more has taken away one of the more important natural disturbances vital to regenerating this forest type. Without fire, regenerating oak following timber removal is difficult, particularly when under the influence of herbivory (i.e., deer browsing, hare and rabbit girdling). Invasive plants (e.g., honeysuckle, buckthorn) and exotic insects (e.g., gypsy moth) can have significant effects on the quality of the wildlife habitat.

** Desired Condition (SGCN Needs):** Oak-Pine-Northern Hardwood Forest should be represented in both large blocks of contiguous forestland that contribute to the full complement of landscape level forest for wide-ranging species, as well as in the natural community types that serve specific SGCN associated with that type. Although contiguous forest blocks are limited in size and availability, where they exist, large, contiguous forest blocks of Oak-Pine-Northern Hardwood Forest will ideally exist in 1,000 acre or more blocks of various elevations and soils. The oak component of this forest serves as important fall foods for numerous mammals, including some key prey species (e.g., deer, small mammals) for wide-ranging wildlife. Because much of the Oak-Pine-Northern Hardwood Forest has been converted to agriculture and development, the remaining fragmented blocks will ideally be maintained, if not enlarged, as well as interconnected through forested or riparian corridors.

**SGCN in Oak-Pine Northern Hardwood Forest**

**High Priority**
- Jefferson Salamander (Ambystoma jeffersonianum)
- Fowler’s Toad (Bufo fowleri)
- Spotted Turtle (Clemmys guttata)
- Wood Turtle (Clemmys insculpata)
- Timber Rattlesnake (Crotalus horridus)
- Eastern Rat Snake (Elaphe obsolete)
- Five-lined Skink (Eumeces fasciatus)
- Hardwood Forest Butterflies
- Tiger Beetles Group
- Indiana Bat (Myotis sodalis)
- Silver-haired Bat (Lasionycteris noctivigilans)
- Eastern Red Bat (Lasiurus borealis)
- Hoary Bat (Lasiurus cinereus)
- Woodland Vole (Microtus pinetorum)
- Southern Bog Lemming (Synaptomys cooperi)

**Medium Priority**
- Northern Goshawk (Accipiter gentilis)
- Long-eared Owl (Asio otus)
- Red-shouldered Hawk (Buteo lineatus)
- Cooper’s Hawk (Accipiter cooperii)
- Chimney Swift (Chaetura pelagica)
- Black-throated Blue Warbler (Dendroica caerulescens)
- American Woodcock (Scolopax minor)
- Chestnut-sided Warbler (Dendroica pensylvanica)
- Ruffed Grouse (Bonasa umbellus)
- Blue-spotted Salamander (Ambystoma laterale)
- Spotted Salamander (Ambystoma maculatum)
- Four-toed Salamander (Hemidactylium scutatum)
- Brown Snake (Storeria dekayi)
- Long-tailed Weasel (Mustela frenata)
- Hairy-tailed Mole (Parascalops breweri)
- Cinereus or Masked Shrew (Sorex cinereus)

**SGCN Note:** Plant SGCN not listed here: 89 species. The SGCN invertebrate groups listed here contain numerous species. For more information about a specific Species of Greatest Conservation Need see that species' assessment summary in Appendix A.

Landscape Level Aquatic and Shoreline Summary

Vermont’s aquatic and shoreline landscape includes all surface waters and their adjacent stream banks, floodplains and/or lakeshores. This landscape includes lacustrine (lake) formations, fluvial (stream and river) formations, floodplain forests, and shores and marshes. This landscape also includes thousands of miles of streambank areas that are comprised of upland communities adjacent to surface waters. The aquatic and shoreline landscape is described as an interconnected system of the lacustrine, fluvial, floodplain, marsh, shore, and upland communities that comprise it for the purpose of identifying and conserving the common habitat functions these communities provide at the landscape level.

Riparian (riverbank) areas, if maintained in continuous, sufficiently wide, interconnected corridors throughout a watershed, serve as movement corridors for many of Vermont’s wildlife species. Maintaining intact terrestrial communities adjacent to surface waters also serves to protect aquatic habitats. Riparian areas help protect water quality, provide organic inputs, regulate water chemistry and physical properties (such as temperature), and provide physical aquatic habitat structure (e.g., undercut banks, large woody debris). Again, because aquatic communities are often inter-connected throughout the landscape, maintaining intact riparian areas is essential to protecting aquatic communities from the headwaters to downstream receiving waters.

Habitat requirements, problems, and conservation strategies have been assessed and developed for both the landscape level, and the individual aquatic and terrestrial species’ habitats that are associated with it. Many SGCN meet most of their habitat needs within the aquatic-terrestrial interface that the aquatic and shoreline landscape provides. These species, in particular, are discussed in this section.

Characteristics and location
Aquatic and shoreline landscapes are comprised of streams, rivers, lakes, wetlands, shorelines and floodplains that form a complex and interrelated hydrological system. This hydrological system extends up and down streams and along lakeshores from the bottom of the water table to the top of the vegetation canopy, and includes land that is directly affected by surface water (Verry 2000). Riparian areas are known for their high biological diversity. They are “characterized by frequent disturbances related to inundation, transport of sediments, and the abrasive and erosive forces of water and ice movement that, in turn, create habitat complexity and variability...resulting in ecologically diverse communities” (Verry 2000).

The landscape level includes both the terrestrial-aquatic interface and the aquatic areas found throughout Vermont, from the mountain streams to the large valley rivers and the lakes and ponds scattered throughout the landscape. The following aquatic and terrestrial areas are...
associated with the aquatic and shoreline landscape (for details see the following summaries in Appendix B):

<td>Upland Shores</td>
</tr>
<tr>
<td>Lake Champlain Tributaries</td>
<td>Wet Shores</td>
</tr>
<tr>
<td>Connecticut River Tributaries</td>
<td>Swamps and Marshes</td>
</tr>
</tbody>
</table>

**Landscape Condition**

**Current Condition:** Nationwide an estimated 70% to 90% of natural riparian vegetation, vital to maintaining the integrity of riparian and aquatic habitats, has already been lost or is degraded due to human activities (Doppelt 1993). In Vermont, some of our rivers, streams, lakes, and wetlands still have intact riparian areas, while many others no longer have functioning riparian areas due to more than 200 years of intensive human use of the land.

In general, riparian areas in Vermont are most affected by habitat conversion, alteration, and fragmentation. Typically, steeper mountainous streams and high elevation lakes and ponds, less suited for human development, have well forested riparian areas with cold, clean water and stable stream channels and shorelines. Recreational activities and their associated development and forestry are the land uses most common in these areas that may affect riparian and aquatic species. Mid and low elevation waterbodies and their adjacent riparian areas are more likely to be impacted by human land uses, including clearing of riparian vegetation, alteration of stream channels and lakeshores, and direct inputs of toxins, excess nutrients, and sediments. These impacts are related primarily to roads, residences, commercial development, and agriculture, with agriculture being especially extensive in the lower valleys of the Champlain and Connecticut tributaries. Lacustrine areas and their associated shorelines are particularly impacted by lakeshore development, such as seasonal and permanent residences, marinas and docks, and public and private beaches. In many instances these developments have altered natural lakeshore and littoral zones resulting in the direct loss of habitats for SGCN through the addition of fill materials (sand, bottom barriers) and the removal of native aquatic vegetation.

The fragmentation of riparian habitat is extensive in Vermont, due primarily to Vermont’s roadways paralleling the stream, rivers, and lakeshores, and use of rich floodplain areas for agriculture. Historic settlement and transportation patterns and ease of construction have resulted in roads paralleling the majority of Vermont’s major waterbodies and thousands of associated bridges and culverts. This results in removal of riparian vegetation and fragmentation, both longitudinally and laterally between the waterbody and adjacent upland communities.

**Desired Condition (SGCN Needs):** Aquatic and shoreline areas provide several habitat functions for the species that inhabit them. Some species rely directly on both the aquatic and terrestrial components of the riparian-aquatic interface. For example, mink and otter use aquatic areas within 100 meters of water’s edge for feeding and riparian areas for denning and as travel corridors. These species move daily between terrestrial and aquatic areas to fulfill their life needs. Other species move seasonally between the aquatic and terrestrial components of the aquatic and shoreline landscape. For example, the wood turtle uses streams and rivers for overwintering, and uses adjacent riparian areas up to 300 meters from
the water’s edge for foraging, breeding, nesting, and dispersal. For those species that are strictly aquatic, the adjacent terrestrial riparian areas function to protect the aquatic areas, providing shade, organic inputs, filtering and storage of overland runoff, and bank stability.

On a landscape level, aquatic and shoreline areas provide habitat for 41 SGCN.

Landscape Fluvial (Stream) Summary

Characteristics and location
There are more than 7,000 miles of rivers and streams in Vermont draining 4 major watersheds: Connecticut, Lake Champlain, Hudson, and Memphremagog. The headwater streams of the western Green Mountains drain to the large rivers of the lower Champlain Valley and eventually into Lake Champlain. The eastern slopes of the Green Mountains drain primarily to the Connecticut River. Portions of the Northeastern Highlands and Northern Piedmont drain north into Lake Memphremagog. The Taconic Mountains and southern Green Mountains drain into the Batten Kill, Deerfield, Walloomsac, and Hoosic rivers. These rivers, with the exception of the Deerfield, eventually drain into the Hudson River in New York. The Deerfield drains to the Connecticut River. Despite this diversity of landscape over which Vermont’s streams and rivers flow, fluvial ecosystems can be described by three general categories based on physical stream characteristics. There are various biotic communities associated with each of these physical stream types, depending on both the physical stream characteristics and the geographic location of the waterbody. For example, the large rivers of the lower Lake Champlain watershed are similar in physical characteristics to the large tributaries feeding Lake Memphremagog, but some of the species found in these two settings differ due to the repopulation patterns of aquatic species into freshwater ecosystems post-glaciation. This summary does not include discussion of the lower Connecticut River tributaries and the lower Lake Champlain tributaries below the fall-line and/or below 150 feet elevation, as these areas are covered under separate summaries.

General types of fluvial communities:

High-elevation Headwater Streams: These streams are typically located in high elevation mountainous areas. They are small in size, having small drainage areas, and are located in steep valleys (typically > 4% slope). Valleys are confined, meaning the stream channel has little or no floodplain, and upland forest communities are adjacent to the channel, typically with no distinct riparian vegetative community present. Channel bed form is usually cascade over bedrock and boulders or step-pools over boulders and cobbles. Stream flow is fast and turbulent with white water common. Stream temperatures are typically very cold. Forest canopy completely shades the stream, and the food web of the system is based on inputs of organic material from the adjacent vegetation (e.g., leaves, twigs, branches). Large trees falling into the stream channel also provide important habitat features and channel bed stability, acting as cover and causing localized scour and deposition of stream sediments. Species that typically inhabit these streams include brook trout, slimy sculpin, northern spring salamander, northern dusky salamander, two-lined salamander, and numerous aquatic insects, including stoneflies and mayflies. SGCN species uniquely associated with these ecosystems include the water shrew, some specific mayfly and Odonata species and naturally reproducing populations of brook trout.

There are some headwater streams in high elevation areas that do not meet the above description. Small, low gradient streams are often found in ridgeline saddles and bowls. These streams are typically meandering, with alternating riffles and pools and gravel and sand substrates. Adjacent wetlands are often associated with these streams. These are typically still cold water systems, due to abundant groundwater feed and cooler climatic
conditions influenced by high elevation, and therefore often host many of the same species as the high gradient headwater streams. Invertebrate communities, however, are likely to be distinct from the higher gradient systems (Burnham 2005).

**Mid-elevation Streams and Rivers:** These streams are typically located in mid elevation areas where the steep mountains transition to the low gradient valleys. Stream channels are small to moderate in size, and are located in moderately steep valleys (typically 2-4% slope). Valleys are semi-confined, resulting in narrow floodplains. These floodplains may have narrow bands of distinct riparian vegetation, but quickly transition into upland forest communities. Channel bed form is typically step-pool or plane bed. Step-pool channels have short vertical drops over boulders and cobbles with channel spanning pools in between, which are typically dominated by cobbles and gravels. Plane bed systems lack distinct pools, and are primarily riffles, runs, and rapids over a mix of boulders, cobbles, and gravels. Stream flow is fast and somewhat turbulent with whitewater common. Stream temperatures are typically cold to cool. Forest canopy usually shades the stream but may not form a complete canopy over the channel. The aquatic food web in these channels is based largely on inputs of organic material from the adjacent vegetation (e.g., leaves, twigs, branches), though some mosses and algae are also present, providing primary production in the waterbody. Large trees falling into the stream channel and transported from upstream provide important habitat features and channel bed stability, acting as cover and causing localized scour and aggradation of the channel bed. Species that typically inhabit these streams include brook trout, slimy sculpin, blacknose dace, white sucker, longnose dace, northern dusky salamander, two-lined salamander, and numerous aquatic insects. SGCN species uniquely associated with this habitat potentially include naturally reproducing populations of brook trout, as well as American eel, Atlantic salmon, wood turtle, river otter, water shrew, mink, muskrat and some specific mayfly and Odonata species.

**Low-elevation Large Valley Rivers:** These rivers are located at low elevations in Vermont’s large river valleys, such as the Winooski, Lamoille, Mississquoi, Barton, Otter, and Batten Kill. This description does not include those portions of the large Lake Champlain tributaries located below the fall-line. These river channels are moderate to large in size, and are located in low gradient valleys (typically <2% slope). Valleys are unconfined, and floodplains are broad and flat. Adjacent wetlands are common in the floodplains. These floodplains have extensive distinct riparian vegetation and often include unique natural communities, such as floodplain forest, marsh, and shoreline communities. The channel bed undulates vertically, being composed of alternating riffles and pools or dune-ripple formations. Riffle-pool systems are dominated by gravels and sands, where dune-ripple systems are usually dominated by sands and silts. Stream flow is slow and flat with whitewater rarely present. Stream temperatures are typically cool to warm. Forest canopy shades the nearbank area of the channel but does not form a complete canopy over the channel. The aquatic food web in these channels is based on inputs of organic material from the adjacent vegetation (e.g., leaves, twigs, and branches) and transported from upstream, as well as instream aquatic vegetation. Large trees falling into the stream channel and transported from upstream provide important habitat features, especially since coarser streambed substrates are typically lacking in these systems. Woody debris provides cover and substrate for aquatic biota, as well as helping to maintain channel bed stability and enhancing habitat complexity with localized scour and aggradation of the channel bed. Numerous cool and warmwater fish species inhabit these streams, including bluntnose minnow, fallfish,
blacknose dace, creek chub, tessellated darter, and white sucker, as well as several mussel species. SGCN species uniquely associated with this habitat include American eel, sea lamprey (Connecticut River drainage only), Atlantic salmon (landlocked and anadromous), blackchin shiner, bridle shiner, blacknose shiner, redfin pickerel, stonecat, giant floater, cylindrical floater, elktoe, brook floater, wood turtle, river otter, mink, muskrat, bald eagle, osprey and some specific species of freshwater snails and Odonata.

Low Elevation Small Streams: These streams are small in size, but located in low gradient valleys (<2% slope) at low elevations (but above the Lake Champlain fall-line and 150 feet in elevation), and typically drain directly into a large waterbody (e.g., Lake Memphremagog, large tributaries of Lake Champlain). Valleys are unconfined, and floodplains are broad, relative to stream size, and flat. These floodplains have distinct riparian vegetation on the valley floor, and transition into upland forest communities on the valley side slopes. Adjacent wetlands are common in the floodplain. The channel bed undulates vertically, being composed of alternating riffles and pools or dune-ripple formations. Riffle-pool systems are dominated by gravels and sands, where dune-ripple systems are dominated by sands and silts. Stream flow is slow and flat. Stream temperatures are typically cool to warm. Streamside vegetation shades the channel, usually forming a closed canopy over the channel. The aquatic food web in these channels is based primarily on inputs of organic material from the adjacent vegetation (e.g., leaves, twigs, branches). Large trees falling into the stream channel provide important habitat features, especially since coarser streambed substrates are typically lacking in these systems. Woody debris provides cover and substrate for aquatic biota, as well as helping to maintain channel bed stability and enhancing habitat complexity with localized scour and aggradation of the channel bed. Typically cool and warmwater fish species inhabit these streams, such as blacknose dace and creek chub. SGCN species uniquely associated with this habitat include American eel, Atlantic salmon (landlocked), blackchin shiner, brassy minnow, bridle shiner, redfin pickerel, stonecat and some specific species of Odonata.

**Landscape Fluvial Condition**

**Current Condition:** In general, fluvial ecosystems in Vermont are most affected by conversion, alteration, and fragmentation. Typically steeper mountainous streams at high elevations, less suited for human development, have well forested riparian areas with cold, clean water and stable stream channels. Recreational activities and their associated development, such as ski resorts, and forestry are the land uses most common in these areas that may affect stream habitats. Mid and low elevation streams and rivers are more likely to be impacted by human land uses, including clearing of riparian vegetation, alteration of stream channels, and direct inputs of toxins, excess nutrients, and sediments. These impacts are related primarily to roads, residences, commercial development, and agriculture, the latter being especially extensive in the lower valleys of the Lake Champlain and Connecticut River tributaries.

The fragmentation of fluvial ecosystems is extensive in Vermont. A recent inventory of more than 200 culverts in the White River watershed showed more than half of the culverts inventoried were barriers to the upstream movement of all fish species present in the waterbody all of the time, and the other half of the culverts inventoried were barriers to some species and/or barriers some of the time (i.e. under certain stream flows when species
movement is likely to occur) (Vermont Fish and Wildlife 2004). In addition, most of Vermont’s major rivers have large flood control and/or hydroelectric dams on them, with numerous smaller dams found throughout Vermont’s smaller streams. Such structures influence local habitat conditions, restrict movement of aquatic species, and alter downstream flood and sediment transport processes. The Vermont Agency of Transportation is currently funding research regarding the extent of stream impediments and how to address issues such as culvert sizing and retrofits.

Some aquatic habitat degradation is due to lasting effects of historic land uses. During the last two centuries land use in Vermont has been dominated by extensive land clearing for forestry and agriculture, aggressive stream clearing of boulders and coarse woody debris for stream log driving and flood control, and by dam construction and railroad and road building. Such activities have resulted in the relocation and straightening of stream and river channels throughout Vermont, resulting in an overall decrease in available fluvial habitat. For example, a recent assessment of the upper White River watershed between Granville and Stockbridge shows that 93% (17.8 of 19.1 miles) of the length of the mainstem White River has been channelized in the past, 13 miles of which are still in channelized form (Vermont Department of Environmental Conservation 2004). In addition, the extensive removal of natural substrates, such as boulders and coarse woody debris, has reduced overall stream habitat complexity throughout the Northeast (Verry 2000). The hard armoring of channels combined with the construction of flood control dams means that many of Vermont’s river channels have not regained their historic sinuosity. Furthermore, the slow regrowth of the Northeast’s forests means that large woody debris contribution to stream and river channels has yet to reach historic levels (Verry 2000). Zadock Thompson, who served as Vermont’s Assistant State Geologist and State Naturalist in the mid 1800’s, offers first-hand insight on the impacts Vermont’s intensive land use history has had on the streams and rivers of the state.

“Before the country was cleared, the whole surface of the ground was deeply covered with leaves, limbs, and logs, and the channels of all the smaller streams were much obstructed by the same. The consequence was that, when the snows dissolved in the spring, or the rains fell in the summer, the waters were retained among the leaves, or retarded by the other obstructions, so as to pass off slowly, and the streams were kept up, nearly uniform as to the size during the whole year. But since the country has become settled, and the obstructions, which retarded the water, removed by freshets, when the snow melts or the rains fall, the waters run off from the surface of the ground quickly, the streams are raised suddenly, run rapidly, and soon subside. In consequence of the water being thus carried off more rapidly, the streams would be smaller than formerly during a considerable part of the year, even though the quantity of water be the same. It is a well known fact that the freshets in Vermont are more sudden and violent than when the country was new.”
Zadock Thompson, Natural History of Vermont, 1853

Desired Condition (SGCN Needs): Most of Vermont’s aquatic species rely on streams and rivers that provide clean water, a diversity of in-channel habitat, and unobstructed movement upstream and downstream between habitats.

Characteristics of water quality vary in streams from clear and cold with little buffering capacity in most mountain streams to somewhat turbid and cool or warm with greater buffering capacity in the large valley rivers. Species found in the mountain headwater and mid-elevation streams are typically dependent on cold well-oxygenated waters. Some species
found in the headwater streams, such as brook trout, are fairly acid tolerant. Low-elevation rivers and streams typically support species with warmer water temperature requirements and tolerance to some turbidity and nutrient enrichment.

Whether in the mountain streams or large valley rivers, most aquatic SGCN require instream cover and/or substrates for protection and colonization. Most fish species seek cover for predator avoidance and to reduce metabolic (energy) demands. Mussels need firm substrates for colonization, as do most aquatic insect species. Substrates utilized may vary from rock to sand to instream aquatic vegetation, depending on the species, but all species can suffer from excessive fine sediments in the channel that can bury instream substrates. Loss of complexity and solid substrates for cover and colonization reduces overall habitat availability and quality. In addition, many species use instream substrates for reproduction. For example, brook trout deposit eggs in gravels on the channel bottom, whereas many shiner species utilize aquatic vegetation to spawn. Embedding of substrates, destabilization of substrates due to chronic channel instability, and direct removal of substrates all impact aquatic habitats and species. The mammal and bird species associated with streams and rivers, such as bald eagle, osprey, mink, river otter, muskrat, and water shrew, are also impacted when aquatic species are affected, as these species rely on aquatic species as prey. In addition, muskrat, otter, mink, and particularly water shrew, utilize undercut streambanks and other stable bank areas for denning. Chronic channel instability that results in substantial streambank erosion may reduce potential denning areas for these species.

Some of the SGCN uniquely associated with streams and rivers have extensive movement requirements, such as the Atlantic salmon and American eel, migrating from freshwater streams and rivers to the Atlantic Ocean and back again. Other species move shorter distances, but still require habitat connectivity to be able to access spawning, rearing, and seasonal habitats. There are also species, such as wood turtle and river otter, that move back and forth between the aquatic and nearby terrestrial habitats both daily and seasonally. Thus, it is important to maintain habitat connectivity both longitudinally along the river channel and adjacent riparian lands, as well as laterally between the aquatic habitat and the riparian habitat.

Ideally, Vermont’s rivers and streams would provide an interconnected network of habitats in which species can move upstream and downstream as needed to fulfill seasonal and diurnal habitat needs. Instream structure would provide an abundance and diversity of habitat niches and be naturally maintained by physical stream processes over time (e.g., flooding, balanced sediment transport). Streams and rivers would be connected to the adjacent riparian habitats, which in turn function to protect and provide for fluvial habitat components, such as instream coarse woody debris and pollutant removal from surface runoff.

It is difficult to quantify the number of miles of intact fluvial and riparian habitat needed to conserve SGCN as the exact distribution of all SGCN associated with fluvial habitats is not known at this time.

Streams and Rivers provides habitat for 25 species and invertebrate groups of greatest conservation need.
Species of Greatest Conservation Need in Fluvial Habitat

High Priority
Bald eagle (Haliaeetus leucocephalus)
Fowlers toad (Bufo fowleri)
Wood turtle (Clemmys insculpata)
River/stream Odonata Group [dragonflies]
Elktoe (Alasmidonta marginata)
Giant floater
Cylindrical floater
Brook floater
Dwarf wedge mussels Group
Freshwater Snails Group
Mayflies/Stonelfies Group
American eel (Anguilla rostrata)
The Atlantic salmon (anadromous) (Salmo salar)
Brassy minnow (Hybognathus hankinsoni)
Bridle shiner (Notropis bifrenatus)
Blackchin shiner (Notropis heterodon)
Blacknose shiner (Notropis heterolepis)
Stonecat (Noturus flavus)

Medium Priority
Osprey (Pandion haliaetus)
Northern river otter (Lutra canadensis)
Muskrat (Ondatra zibethicus)
Mink (Mustella vison)
Water shrew
Redfin pickerel (Esox americanus)
Brook trout (Salvelinus fontinalis)
The Atlantic salmon (landlocked) (Salmo salar)

SGCN Notes: Lake sturgeon is addressed in the Lake Champlain tributaries summary. Plant SGCN not listed here: 16 species. The SGCN invertebrate groups listed here contain numerous species. For more information about a specific Species of Greatest Conservation Need see that species’ assessment summary in Appendix A.

Problems & Information Needs

Monitoring & Adaptive Management

This section of the Action Plan outlines plans to track the status of Species of Greatest Conservation Need (SGCN), evaluate and improve the effectiveness of conservation strategies and provide data to keep the Action Plan report up-to-date.

Adaptive Management
Elements five and six of the Eight Required Elements of a Action Plan outline Congressional expectations for monitoring and plan review in the Action Plan report. Specifically element five requires that states provide:

Proposed plans for monitoring species [of Greatest Conservation Need] and their habitats, for monitoring the effectiveness of the conservation actions proposed in the 4th element [strategies], and for adapting these conservation actions to respond appropriately to new information or changing conditions.

Element six requires that states provide:
Descriptions of procedures to review the strategy at intervals not to exceed ten years.

Just as a doctor checks a patient's blood pressure at every visit, wildlife monitoring allows biologists to identify changes in the health of wildlife (e.g., population changes, the spread of disease, changes to the landscape). Wildlife biologists can also monitor the impact of strategies to determine effectiveness just as doctors assess the efficacy of treatments and compare competing medical practices. The goal is not simply to cure one patient but improve the understanding and standard of care for all patients.

Taken together elements five and six speak to the need for an adaptive management program to track changes in wildlife populations and hone the effectiveness of conservation strategies. Adaptive management is a formalized method for learning from experience (Fig 1) where design, management, and monitoring are integrated to test assumptions in order to adapt, learn and improve (Salafsky et. al. 2001). Instead of relying on a fixed conservation goal and an inflexible plan for achieving the goal, adaptive management allows for midcourse corrections.

In the initial planning phase our Action Plan Species Teams and the Integration Team spent many hours evaluating data, identifying problems limiting SGCN and habitats. They
then developed hundreds of conservation strategies and research recommendations that the Vermont Fish & Wildlife Department (VFWD), Conservation Partners and others could begin to implement during an action phase. Measuring the effectiveness and success of the plans and actions occurs in the monitoring phase. The cycle begins anew with the fine-tuning of goals and objectives before action is renewed.

Monitoring is a linchpin in the adaptive management process. Monitoring is also a complex, demanding and never-ending task. With VFWD, sister departments at the Agency of Natural Resources, conservation partners, other local and federal agencies, academic institutions, non-governmental organizations and even individuals engaged in a broad range of wildlife and habitat monitoring projects, before any new monitoring programs are initiated a review of existing efforts and careful planning are required.

**Current Survey and Monitoring of Vermont Wildlife**

A list of current survey and monitoring projects that may provide relevant data for the conservation and management of SGCN is remarkably long. The Fish & Wildlife Department along with the Department of Environmental Conservation (DEC) and other conservation partners monitor state and federally designated threatened and endangered species, and some rare species and uncommon natural communities. VTrans in coordination with VFWD is recording road mortality data on the state highway system. Additionally data from wildlife surveys are regularly collected by VFWD’s Nongame & Natural Heritage Program (NNHP). Many of these surveys, however, are not repeated enough to provide population trends, nor are they sufficient in extent to provide statewide estimates. In general baseline distribution and abundance estimates for SGCN has never been determined. Population trends, habitat availability or impacts of threats are similarly unknown. Nonetheless, any new monitoring efforts should build on these and other existing monitoring programs, as well as the expertise of the VFWD, conservation partners and others within Vermont, regionally and nationally.

The following is a cursory review of survey and monitoring efforts in Vermont that may benefit SGCN conservation and management. It is not meant to be comprehensive.

**Birds:** Birds are the most studied and best monitored group of wildlife in Vermont—and nationally. Key Vermont monitoring efforts include the Breeding Bird Atlas (Vermont Institute of Natural Science (VINS) & VFWD—sponsored by the State Wildlife Grants program (SWG)), the annual Breeding Bird Surveys (NABCI), and the Common Tern, the Important Bird Area and the Marshbird Monitoring programs (Audubon). The Vermont Institute of Natural Science has maintained bird data since 1974 with the eBird Online database. VINS also manages the Mountain Birdwatch, Forest Bird Monitoring Project, Loon Recovery Project, the Peregrine Falcon recovery program (with VFWD) and monitors of Bicknell's thrush on Hispaniola and of bobolink in Paraguay and Bolivia. A multi-party effort is underway to restore and monitor bald eagles in state. Other species-specific and guild-specific monitoring occurs for, osprey, American woodcock, turkey, waterfowl, and double crested cormorants. Regional and national monitoring efforts include the Breeding Bird Survey and Atlantic Coast Joint Venture.
Fish: Historically referred to as "vermin fishes" (Greeley 1930) and "trash fish," the species not prized by anglers have not been the focus of fisheries biologists either. More recently a variety of entities have been conducting surveys on a broader range of fish including some SGCN. *Fishes of Vermont* (Langdon et. al. in prep) is supported by DEC's 9,000 record fish distribution database. Non-native invasive species, such as alewife and zebra mussel, are also the subject regular surveys.

Invertebrates: Mussels may be best monitored of all Vermont invertebrates with semi-permanent survey stations in place. The SWG sponsored Vermont Butterfly Survey; a citizen science-based monitoring program coordinated by VINS is Vermont's first state-wide systematic inventory of invertebrate species. Some invertebrate monitoring occurs for pest species (FPR and Agency of Agriculture), as indicators of water quality (DEC) for several threatened and endangered invertebrates such as tiger beetles (3 species) and mollusks (10 species). DEC's water quality monitoring employs an index of integrity based on the composition of invertebrates in water bodies. Some taxon-wide surveys include moth surveys at Ethan Allen Firing Range (Griggs and Grehan 2000) and Mount Mansfield (Griggs and Grehan 2001). Nevertheless, most invertebrate taxa remain largely uninvestigated and unknown in Vermont. There remains a serious need for basic background survey work to document the presence and distribution of major orders of insects in Vermont, notably Odonata (dragonflies and damselflies).

Mammals: Deer, moose, black bear and furbearing species are closely monitored by VFWD. Keeping Track, Inc. has citizen monitoring teams in many sections of the state and region collecting long-term data on black bear, bobcat, moose, fisher, river otter, and mink. Threatened and Endangered species include American marten, and Canada lynx. Monitoring of several bat species in certain regions of the state has begun in the past three years funded by SWG. Most other mammals, particularly small mammals, have not been monitored historically and no baseline data is available. Numerous individual localized surveys have occurred in the past but no ongoing, repeatable monitoring have not taken place.

Reptiles & Amphibians: The Vermont Reptile and Amphibian Atlas (Middlebury College) is an ongoing citizen science research and monitoring project begun in 1995 to determine the distribution of reptiles and amphibians in Vermont. Additionally monitoring for some threatened and endangered reptiles and amphibians is conducted by VFWD, and DEC initiated Northern Leopard Frog surveys in 1996 in response to reports of malformed frogs in the Lake Champlain Basin.

Current Habitat and Vegetation Monitoring in Vermont

- Coordinated wildlife surveys (songbirds, reptiles, amphibians, and selected mammals—black bear, fisher, and bobcat) were conducted statewide in 2003-2004 by the Vermont Cooperative Fish and Wildlife Research Unit (VT Coop). These surveys provide a consistent statewide, on-the-ground baseline data for monitoring and results will inform predictive occurrence models for multiple taxa (T. Donovan, VT Coop), personal communication).
• The Ambient Biomonitoring Network program was established by DEC’s Water Quality Division 1985 to: monitor long-term trends in water quality as revealed in changes over time to ambient fish and aquatic macroinvertebrate communities; to evaluate site-specific impacts of point and non-point discharges to aquatic biological communities, and to establish baseline data to assist in establishing Vermont-specific biological criteria for water quality classification attainment determinations in lakes, wetlands, rivers, and streams (DEC 2004b).

• The Long-Term Water Quality and Biological Monitoring Project for Lake Champlain began in 1992. A joint effort shared by DEC and the New York State Department of Environmental Conservation the n 1995, the primary purpose of the project is to detect long-term environmental change in the lake.

• The Vermont Wetlands Bioassessment Project is a coordinated effort between DEC and NNHP to document and understand biological and physical characteristics associated with vernal (seasonal) pools and northern white cedar swamps in the state (DEC 2004b).

• A joint Agency of Transportation-VFWD wildlife road crossing project is identifying significant wildlife travel corridors and road crossings to help reduce roadkill and improve future road design and placement.

• The Forest Inventory and Analysis (FIA) is a recurring inventory conducted by the US Forest Service's FIA Unit of the Northeastern Research Station in conjunction with the Vermont Department of Forests, Parks & Recreation. The inventory provides data for measuring changes and trends in the extent and condition of forest land, associated timber volumes, and rates of timber growth, mortality, and removal (Wharton et. al 2003). Though this information is developed primarily for timber management and does not track old-growth forests it does provide important information to wildlife managers.

• The National Resources Inventory program of the National Resource Conservation Service (NRCS) collects and distributes data on a state, regional and national level about the status, condition, and trends of soil, water, and related resources. The focus is primarily on agricultural lands with data includes available land-use types and land-use changes, erosion, and wetlands.

• The Gap Analysis Project (GAP) sponsored by the US Geological Survey (USGS) provides nationwide land cover data that can be used to identify lands important to wildlife and the extent to which habitat for native animal and plant species are being protected. A revised Vermont/New Hampshire GAP report is expected in 2007 (USGS 2005).

• The Vermont Monitoring Cooperative (VMC) coordinates numerous monitoring and survey operations in Vermont focusing primarily on forest health issues.

• The Nongame and Natural Heritage Program conducts ongoing natural community inventory identifies and maps natural community types statewide. A survey and
report on the distribution, ecology, classification of hardwood swamps was completed in 2004. NNHP also updates and maintains data on known and mapped significant natural communities, maps natural communities on state land and works with non-governmental organization partners to map or identify significant natural communities on NGO lands.

- Habitat Loss and fragmentation: the Vermont Forum on Sprawl can provide research, tools and training to track changes to habitat due to development. Also the NRCS State Office is creating a GIS layer urban and built-up lands by County. This GIS-based data may be helpful in efforts to assess habitat fragmentation.

What Kind of Monitoring Is Needed to Successfully Implement the Wildlife Action Plan and Conserve SGCN?

In addition to monitoring the status, trends and problems impacting SGCN populations, an adaptive management program requires implementation, effectiveness and validation monitoring (Derr et. al 2005) to ensure that goals and objectives are achieved and SWG funds are spent wisely:

- **Implementation Monitoring:** Assessing the degree to which a conservation strategy was implemented (e.g., were trees planted in a riparian area?).
- **Effectiveness Monitoring:** Measuring the impact or effect of a conservation strategy (e.g., did planting trees in the riparian area stabilize the streambank?—the strategy’s objective).
- **Validation Monitoring:** Checking the assumptions upon which the conservation strategy was based (e.g., did stabilizing the streambank actually reduce sedimentation of spawning beds downstream, producing more salmon fry? —the strategy’s objective). Validation monitoring can help answer questions such as: Is the conservation strategy worth repeating or might another strategy produce results faster, more economically, or meet with better social acceptance?

The Fish & Wildlife Department already has implementation and financial monitoring protocols operating for State Wildlife Grants-funded projects. SWG project managers have 90 days from completion of a project to submit a draft report to the VFWD Division Director associated with each project. Division Directors review and edit the report and are responsible for final approval of all reports. Upon final approval reports are submitted to the US Fish & Wildlife Service Division of Federal Assistance for review.

SWG project managers review expenditure tracking reports report according to a regular schedule each year. Financial reporting of all in-kind match is required annually. Project managers are responsible for securing this information from third-parties organizations and contractors. The VFWD business office also tracks and documents third party match.

Though critically important, effectiveness and validation monitoring may not be practical or possible for each SWG funded conservation project (e.g., small scale, dispersed, technical support). Effectiveness may take years to determine (e.g., waiting for trees to grow to
sufficient height to shade a stream) and validation of a strategy's success may be difficult to tease out from other problems impacting a species or a site (e.g., the strategy did produce more salmon fry but the results were masked two unseasonably hot summers and an accidental chemical spill). SWG administrators and planners may want to focus conservation efforts on specific species and/or regions of the state (e.g., selected watersheds) for periods of time sufficient to ensure that the cumulative conservation efforts can be measured effectively. The demonstration projects can be rolled out to the elsewhere in the state after evaluation proves their utility.

Primary Challenges to the Implementation of a SGCN Monitoring Program

Pursuant to Congressional requirements Action Plan technical teams identified priority monitoring needs for every SGCN. Performance measures were also developed aid in implementation and effectiveness monitoring of Action Plan conservation strategies. However plans to implement a comprehensive monitoring program will first have to address four overarching issues:

1. Financial and staffing resources are insufficient to manage the current volume of wildlife survey and monitoring data developed by resource professionals.
2. Little data exists for most SGCN (lack of data was one criterion for selection as a Species of Greatest Conservation Need). Developing baseline distribution and abundance estimates is the first step in monitoring populations.
3. Despite SWG funds, financial resources are insufficient to support individual monitoring programs for 143 vertebrate and 188 invertebrate Species of Greatest Conservation Need.
4. Consistent protocols and systems for data collection and data sharing do not exist. Without the ability to collect and share data opportunities are lost and efforts can be duplicated.

To be successful, any Action Plan monitoring program will need to address these four challenges. It is hoped that the Action Plan and SWG funds will help direct future research and development efforts, facilitate the integration of existing monitoring projects across organizations and improve collaboration.

Adapting Conservation Actions in Response to New Information or Changing Conditions

White-tailed deer, the most closely watched animal in the state, underscores the need to adapt management to changing conditions and information. Vermont's deer management plan was crafted by many experts with seemingly limitless oversight and review. The recent finding of chronic wasting disease in the New York deer population, however, significantly changed the landscape for deer management in the region. New legislation, rules and procedures to protect the herd and the public were designed and implemented within weeks of confirmation of the initial findings. Action Plan monitoring and review procedures will be the primary tool to identify new information, changing conditions and the need for
adaptation. It will act at three scales—individual conservation projects, ongoing plan-wide adaptations (year-to-year), and 10-year plan review.

The iterative nature of adaptive management (plan → implement → monitor → evaluate → plan → …) builds opportunities to adapt directly into Action Plan project management activities. Project reporting, monitoring and the increased communication and coordination among conservation partners fostered by Action Plan implementation will feed into overall Action Plan management from year-to-year. All this information will be used to formally review and revise the Action Plan on a 10-year cycle (see also Action Plan Review later in this chapter).

Plans for Monitoring SGCN, Habitats and Conservation Actions

A statewide wildlife monitoring and adaptive management program is needed to measure progress toward desired outcomes for SGCN, their habitats, to evaluate and improve the effectiveness of conservation strategies, to adapt conservation actions to new information or changing conditions and to sustain the effectiveness of strategies in attaining desired outcomes. There was insufficient time to develop such a complex and important program prior to the October 1, 2005 deadline for Action Plan completion. In the coming months the Vermont Fish & Wildlife Department will initiate a collaborative process to develop and implement a statewide wildlife monitoring and adaptive management program to answer the following questions (adapted from USFS 2004, Schoonmaker and Luscombe 2005):

- What are the status and trends of SGCN, their habitats, and other important communities for which there are not specific anticipated outcomes (e.g., invasive species)?
- What are the areas of land and water within each biophysical region that will provide the best opportunities for conservation actions for SGCN and habitats?
- Were planned conservation actions carried out?
- Are SGCN and habitats responding to the conservation actions as anticipated?
- How does new information compare with previous information or expectations?
- Who is implementing these actions?
- What are the costs of conservation actions?
- Are objectives consistently being achieved with outcomes as anticipated?
- How are stakeholders responding to conservation actions and Action Plan implementation?

Major guidelines for the development of this Action Plan monitoring program include:

**Collaboration:** Planning to develop and implement a Species of Greatest Conservation Need monitoring program should begin with collaboration. As with the design of conservation strategies in this report, successful monitoring of SGCN will require the help
and cooperation of many partners. Many current survey and monitoring efforts are conducted by interagency and inter-organizational efforts locally, regionally and nationally. These collaborations share expertise, make the best of limited resources, prevent redundancies of effort, increase the level of expertise of volunteers and improve program quality and effectiveness.

How much collaboration is needed? As many entities as possible should be brought together to develop consistent monitoring protocols and systems for data collection and data sharing, identifying indicators for species and habitats and goals and objectives for SGCN conservation.

The need for collaborative fund raising efforts cannot be overstated. Sufficient funds are imperative for monitoring to be effective. The State Wildlife Grants program currently is not sufficiently funded to finance the monitoring needs outlined here. Even if it was, state-side match is insufficient. A collaborative effort of agencies, conservation partners, local, state and federal elected officials, NGOs and private businesses and individuals is needed to develop adequate funding mechanisms at the state and federal levels.

**Coordination:** The coordination of monitoring programs, summarizing of results and sharing data with resources managers, researchers, local, state and national decision makers, educators, stakeholders and the general public will be essential to the success of a monitoring collaborative, to Action Plan efforts and to wildlife conservation in general. Solid coordination throughout the implementation phase will also make revisions of the Action Plan report straightforward and uncomplicated.

**Baseline data:** Distribution and abundance information for SGCN and their habitats are needed in order to establish meaningful baseline data. This data will be used to determine measurable goals and objectives that are the foundation of monitoring priorities.

**Indicators:** Monitoring every SGCN, their habitats, problems and the effects of conservation actions is too costly and time-consuming to ever complete. Relevant indicators that are measurable, precise, consistent, and sensitive are needed as coarse filters to make monitoring useful and manageable. Indicators should also be of appropriate scale, easily obtained and obvious in meaning so that results can be supported by a broad array of users.

**Citizen Science:** Successful monitoring projects such as VINS' Bird Atlas, Butterfly Survey and LoonWatch, the Vermont Reptile and Amphibian Atlas, Keeping Track Inc.'s big mammal monitoring, Audubon's Christmas Bird Counts, Marshbird Monitoring, and Great Backyard Bird Count and VFWD's Big Game Report Stations provide multiple benefits that should be considered in the development of new monitoring efforts. In addition to the direct benefits—improved wildlife knowledge—citizen-based monitoring also provides wildlife education through active field work on local projects, boosts awareness of and involvement in natural resource protection at the community level, and can be highly cost-effective.
Resources for Developing Vermont’s Action Plan Monitoring Program
Baseline Wildlife Data and Predictive Models for Wildlife Distribution and Land-Use Change: A long-term study by the VT Coop will soon help determine the distribution of a diverse array of terrestrial species: predict how land use will change over time; and, predict how occurrence of biodiversity will change in response to land use change (T. Donovan, VT Coop, personal communication). In 2003-2004 coordinated wildlife assessments (songbirds, reptiles, amphibians, and selected mammals—black bear, fisher, and bobcat) were conducted statewide. Results will inform predictive occurrence models for multiple taxa. Importantly, these surveys provide the first statewide, on-the-ground baseline data for monitoring changes in biodiversity over time. Land use change will be modeled under multiple policy scenarios, including no change in current policies. The corresponding impact on biodiversity will be quantified for each policy scenario. Finally, spatial optimization methods will be used to identify land use patterns that are optimal for conserving an array of species, subject to socio-economic constraints. The result will be a decision-making tool that informs stakeholders of how projected land use change scenarios will likely affect different levels of biodiversity. The Unit intends to repeat these surveys on a 5-10 year cycle for long-term monitoring purposes.

Habitat-Based Monitoring for Assessing Conservation Strategies: Habitat Monitoring: an Approach for Reporting Status and Trends for State Comprehensive Wildlife Conservation Strategies (Schoonmaker and Luscombe 2005) was commissioned by Defenders of Wildlife expressly to help states develop their Action Plan monitoring programs. This report provides a framework to track and assess the effectiveness of conservation actions and to adapt proposed conservation actions as needed in response to new information and changing conditions. It includes guidance for developing conservation goals, building habitat baseline data, and detecting changes over time to measure outcomes. Species monitoring is not addressed in detail. The paper stresses the importance of building a constituency of involved stakeholders and ensuring that the development of a wildlife conservation strategy and monitoring program is a goal-driven process.

VMC as a Model for Coordination of Statewide SGCN Monitoring: The Vermont Monitoring Cooperative (VMC) (http://vmc.snr.uvm.edu) is a collaborative partnership that collects and pools information and data on Vermont’s forested ecosystems. Participating cooperators from government, academic and private sectors, conduct research projects on a variety of topics including forest health, air quality and meteorology, wildlife and aquatic systems. The VMC makes the data and results from these projects available to other scientists, educators, resource managers and the general public through its online data library and card catalogue containing the data and metadata from more that 100 projects.

All-Bird Monitoring as a Model for Statewide SGCN Monitoring Programs: The science and reach of bird monitoring far exceeds monitoring programs for other taxa. The “All-Bird monitoring” programs coordinated by North American Bird Conservation Initiative (NABCI) (http://www.nabci-us.org/) should be the bases for bird monitoring in Vermont. Furthermore the development of monitoring protocols for other taxa can benefit from a review of these bird monitoring programs.

Reptile and Amphibian Monitoring: In addition to Vermont's Reptile and Amphibian Atlas, two other initiatives are developing monitoring protocols for reptiles and amphibians.
Partners in Amphibian and Reptile Conservation (PARC) (http://www.parcplace.org/) and Amphibian Research and Monitoring Initiative (ARMI) (http://armi.usgs.gov/). Both entities should be involved in the development of monitoring plans for Vermont.

**Comprehensive Water Monitoring and Assessment Program:** To ensure that states are responsible for implementing the Clean Water Act, the U.S. Environmental Protection Agency (EPA) requires that states develop a comprehensive water quality monitoring and assessment program to track environmental conditions and changes over time, to help set levels of protection in water quality standards, and to identify problem areas that are emerging or that need additional regulatory and non-regulatory actions to support water quality management decisions (EPA 2003).

**Land Type Association Modeling/Mapping:** In 2005 the Vermont Department of Forest, Parks and Recreation, The Nature Conservancy and the US Forest Service have started a project to define Land Type Associations (LTA) throughout the state. Land Type Associations describe landscapes of matrix communities (1,000's of acres) based on factors such as bedrock and surficial geology and soil types. The primary purpose of this project is to correlate LTA's with insect and disease outbreaks to aid forest management. Data from this project, particularly the baseline mapping data, can be helpful to wildlife and habitat monitoring.

**The Montréal Process** is an international working group formed in 1994 to develop and implement internationally agreed upon criteria and indicators for the conservation and sustainable management of temperate and boreal forests http://www.mpci.org/.

**Data storage and data sharing:** The volume of government (local, state, federal), NGO, and private sectors data available for plants, animals, ecosystems, climate, geology, hydrology, social and economic that could be used to conserve wildlife is simply huge. The management, storage and accessibility of monitoring data will be a significant issue for any coordinated monitoring efforts. Vermont's NNHP manages much of the current wildlife data in collected in Vermont but the program is already understaffed. Additional resources that may be of assistance in data storage and data sharing include:

**The National Biological Information Infrastructure (NBII) (www.nbii.gov)** is a broad, collaborative program led by the Center for Biological Informatics of the U.S. Geological Survey. The NBII links biological databases, information products, and analytical tools maintained by NBII partners and other contributors in government agencies, academic institutions, non-government organizations, and private industry. NBII facilitates also work on new standards, tools, and technologies that make it easier to find, integrate, and apply biological resources information.

**NatureServe:** (www.natureserve.org) represents an international network of biological inventories—known as natural heritage programs and conservation data centers—operating in all 50 U.S. states, Canada, Latin America and the Caribbean (NNHP is the Vermont affiliate to NatureServe). NatureServe collects and manages data on rare, threatened and endangered plants, animals, and ecosystems, establishes scientific standards for biological inventory and biodiversity data management, and develops data management tools.

Action Plan: Implementation

Congressional intent for the Wildlife Action Plan project is to identify and address the needs of all wildlife species in the state that might require help in order to prevent their becoming threatened or endangered. The full import of the word “comprehensive” becomes overwhelmingly clear as numbers in this report are tallied. (1,349 problems identified, 593 conservation strategies (setting the stage for hundreds or thousands of potential conservation actions), for 143 vertebrate species, 188 invertebrates, 577 plants and more than 100 habitat/community/landscape categories). The next steps, conducting the recommended research, setting species and habitat goals and objectives, implementing strategies and designing and implementing the monitoring programs outlined in this report requires the continued help and support of all conservation partners—those that participated in the Action Plan development and new partners as well.

Congress has designated state Fish & Wildlife Departments as Action Plan and State Wildlife Grants (SWG) custodians because they are the entities mandated by state law to manage and protect wildlife. Custodial responsibilities include not only delivering the completed Action Plan by Oct 1, 2005 but also for regular review and updating of the Action Plan report and administrating SWG funds. To carry out these responsibilities the VFWD will assign sufficient staff and resources to this program to manage projects, coordinate efforts and monitor overall program operations.

The VFWD will take the lead in coordinating the implementation of the research and monitoring recommendations and conservation strategies described in this report. While the department may be responsible for implementing much of the research, monitoring and conservation strategies, it will be Conservation partners, however, that may be the more logical and appropriate leaders for other research and strategy implementation, due to their skills and expertise, staffing, history, location, available resources and constituencies.

The Action Plan will remain a work in progress for many years, an experiment in long-term multi-species conservation on a scale not experienced before. Much of the work in this document is ground breaking. Many of the species examined here have not received focused attention before. The next few cycles of implementation, review and updating of individual strategies and the Action Plan report overall will be the particularly important for working out kinks, testing methods, and improving aspects of the Action Plan.

Implementation and Participation

As a wildlife conservation plan for the entire state, the Action Plan includes some strategies that almost any individual or organization can implement. Any and all interested partners are encouraged to take part. Though many of these actions will not require the notification of VFWD, tracking the implementation and outcomes of each action is vital to the monitoring and adaptive management goals outlined elsewhere in this chapter. All participating partners are encouraged to consult with VFWD prior to taking action.

Impacts on other species, habitats and ecological processes and functions should always be considered when implementing conservation actions to benefit Species of Greatest
Conservation Need (SGCN). Implementation may also be subject to changing conditions and regulatory review (where required) and should be conducted in cooperation with land managers, land owners and key stakeholders. Large scale conservation efforts (e.g., broad scale monitoring) should be coordinated through VFWD, interagency workgroups and formal agreements where applicable.

Coordination and Collaboration
As noted throughout this report, coordination of efforts is vital to leveraging available resources to ensure maximum wildlife benefit. VFWD will take the lead in facilitating communications among Conservation Partners, including local, state and federal agencies, through email networks, SWG annual reporting and a yearly conservation partner meeting open to any and all interested parties.

Coordination between states (regionally and nationally) will be spearheaded by the International Association of Fish & Wildlife Agencies (IAFWA) and the US Fish & Wildlife Service. Plans are already underway to help states effectively implement their Action Plans, to facilitate projects spanning multiple states and to improve agency capacity to implement their Action Plans (IAFWA 2005).

Prioritizing Conservation Need
During the identification and assessment of SGCN our Action Plan technical teams began the process to prioritize conservation need through the following actions: SGCN were assigned either medium or high priority status (low priority species are deemed relatively secure for now, see Action Plan development, chapter 3 for ranking criteria), species conservation strategies, research and monitoring needs and habitat problems were ranked medium and high based on the combined expertise of each technical team.

We did not prioritize needs and strategies beyond this. The Action Plan is a conservation guide for the state—not only VFWD or the Agency of Natural Resources. It is meant to provide guidance to organizations, agencies and individuals who wish to conserve wildlife. The goals and missions of the many and varied partners involved in the project span a broad spectrum of wildlife interests, skills and reach (some are very local, others are state, regional and federal entities). It was clear that there would be no prioritization that would satisfy all partners and that conservation need is so great that there is room for everyone to select the species and habitats they find most important and implement the strategies they are most capable of working on.

When it comes to allocating SWG funds to specific projects, further prioritization is required. Prioritization will take into account the goal of the SWG program—to keep wildlife populations from declining to the point that they require protection under the federal Endangered Species Act (ESA)—and Congressional intent—that SWG funds benefit wildlife that have not historically been the primary beneficiaries of the Federal Aid in Wildlife Restoration Act, Federal Aid in Sport Fish Restoration Program or the federal ESA. Prioritization will also be based on the impact of problems to SGCN and habitats, the project's ability to affect positive change, other conservation and social impacts and the
availability of matching funds (see the draft process outlined below and Appendix J for the SWG Competitive Grants Proposal Evaluation form).

**Conservation Opportunity Areas:** The Action Plan monitoring program (discussed earlier in this chapter) will help identify areas of land and water within each biophysical region that provide the best prospects for conservation actions to benefit SGCN and their habitats. VFWD and partners can prioritize (though not limit) efforts on these "Conservation Opportunity Areas" in order to achieve a greater likelihood of success and to use limited conservation funds most efficiently.

**Implementation Funds and Resources**
Most of the conservation strategies in this report are eligible for State Wildlife Grants program funds, and there is the rub. Conservation need and opportunity far outstrip current financial resources. To strategically allocate funds to the species and habitats in greatest need and to those projects that are likely to show the most promising results, we have drafted a process for soliciting, evaluating and selecting projects to receive SWG funding. That process is described in the next section below.

Agencies, organizations and individuals seeking funding for Action Plan conservation projects through sources other than SWG are encouraged to reference the Action Plan in grant applications and seek letters of support from other Conservation Partners including the VFWD. Entities wishing to implement conservation strategies should consider calling on the VFWD and other Conservation Partners for their expertise, advice, training and needed equipment and where appropriate collaborations should be considered.

**Allocating State Wildlife Grant Funds**
Congress, through annual Interior Appropriations legislation has allocated funds to the State Wildlife Grants program yearly since 2001. Vermont’s share of these appropriations has averaged approximately $600,000 each year. Interior appropriations bills are generally approved in the fall of each year. In the spring of the following year VFWD submits proposals for use of SWG funds to the US Fish & Wildlife Service Division of Federal Assistance (USFWS-FA), the entity responsible for administering and managing the SWG program nationwide. Funds for accepted proposals are made available later that year and will generally remain available several years thereafter. A portion of each year's SWG appropriation will be made available to Conservation Partners for Action Plan implementation through a grants program. All eligible entities may submit applications.

The following is an outline of the draft schedule and process for applying and selecting recipients of SWG grant funds. Full procedures and proposal guidelines will be ready in October 2005.
Timeline / Process (draft)

November: The VFWD determines the availability of funds for the coming year and the percentage of funds available for the SWG Small Grants program (this determination may be delayed if the federal budget is not approved on time, as is sometimes the case).

November/December: Meeting of Conservation Partners to discuss the past year’s progress on Action Plan implementation and needs and opportunities for the coming year. Recommendations will be taken regarding the proportion of SWG funds to be allotted to conservation categories such as research, monitoring, habitat restoration, species recovery activities, etc. Final allocation will be determined by the VFWD Grants Committee (see below).

December: A request for proposals for use of SWG funds for Action Plan implementation will be announced by VFWD.

March Proposal submission deadline.

March-May Proposals will be reviewed as follows:

**SWG Coordinator** (VFWD staff): reviews proposals for completeness and eligibility. Complete proposals that meet the minimum eligibility standards are deemed accepted and are sent to the SWG Technical Committee.

**SWG Technical Committee** (VFWD staff and selected Conservation Partners): reviews & scores accepted proposals. Scoring will be based on draft criteria found here in Appendix J. The Technical Committee selects a slate of recommended proposals. All proposals are sent to the Grants Committee.

**Grants Committee** (VFWD Division Directors and NNHP Coordinator): The Grants Committee selects finalists from both within and outside the Department based on proposal scoring, recommendations of Technical Committee, available funds and Department priorities.

**VFWD Commissioner**: receives finalists from Finalists are sent to the Commissioner for final approval.

Action Plan Review

Element number six of the eight required elements for an Action Plan (see Chapter 1: Congressional Guidelines) requires that states provide “descriptions of procedures to review the strategy at intervals not to exceed ten years.”

Vermont will update its Action Plan on a 10-year cycle. Ten years will allow for planning, and implementation of actions and for detectable responses for many SGCN. Vermont’s adaptive management approach to Action Plan implementation, however, means that species and habitat monitoring, formal project reporting and financial tracking will be ongoing and will provide a constant flow of information during the intervening years. Managers, wildlife planners and biologists will use this data to hone strategies, fine tune operations and make mid-course corrections within each ten year cycle. Review activities will include:

- Twice yearly expenditure tracking for individual projects by SWG project managers.
- Annual financial reporting of all in-kind match for individual projects by SWG project managers.
- Full project reports due within 90 days of completion of Individual SWG projects by SWG project managers.
- Providing regular Federal Assistance reports to the US Fish & Wildlife Service Division of Federal Assistance.
- A biannual Action Plan meeting for Conservation Partners will be organized by VFWD to review the year’s efforts, identify goals for the coming year and to share information about Vermont SGCN, successes, obstacles and needs related to wildlife conservation and Action Plan project implementation.
- A biannual report on the Action Plan to stakeholders, the general public and policy makers will review the past year’s efforts and outline goals for the coming year.

Interstate Coordination and Information Sharing

With 49 other states and 6 territories all implementing their own Strategies in the coming months it is likely that there will be successful projects and programs that could benefit Vermont SGCN. There will undoubtedly be many regional and national efforts to share this information. Vermont should make it a priority to attend these meetings and perform a thorough review of methods and results from other states.
Ten Year Review
The process to review and update the Action Plan in 2015 should begin at least two years prior to the deadline. The current thinking is that the review process should mirror the original Action Plan development process. This will include full participation by Conservation Partners (including local, state and federal agencies) on teams and committees, analyses of the work completed to date, evaluation of monitoring data and the updating of each of the eight elements from the original congressional guidelines as follows:

1) Revise the list of SGCN and update information on the distribution and abundance of SGCN. Which species can be removed from the list, which should be added?

2) Update information on the location and condition of key habitats. Describe key habitats of any new SGCN.

3) Describe threats and problems impacting SGCN and their habitats. Update research needs.

4) Review the success of conservation actions implemented to date. Identify conservation actions to conserve SGCN and their habitats.

5) Review Action Plan monitoring efforts to date. Describe plans to monitor species, habitats and conservation actions for the future.

6) Update and describe the process for the next plan review.

7) Review coordination efforts to date. Update plans to coordinate with other plans and planning entities.

8) Revise and describe plans to include the public in the design and implementation of the next Action Plan report.
Chapter 6: Vermont Wildlife Action Plan Glossary & Acronym Key

This glossary contains definitions to many of the terms used in this document.

**Actively managed:** For wildlife this means that a management plan for the species or a suite of species exists. (E.g. an osprey plan, waterfowl plan, spruce grouse plan.)

**Anthropogenic:** Conditions that result from human activities. “Anthropo-” meaning human and “-genic” meaning produced from.

**Comprehensive Wildlife Conservation Strategy (CWCS):** This Wildlife Action Plan was developed under the working title of Comprehensive Wildlife Conservation Strategy (CWCS). Upon federal approval the name was changed to Wildlife Action Plan (Action Plan). The Action Plan/CWCS sets a plan of action for conserving Vermont's wildlife by addressing conservation issues, management needs, and priorities. It is intended to be used by anyone with an interest in wildlife conservation.

**Conservation:** Plans and actions that will help restore and/or sustain Vermont's wildlife populations, with a focus on Species of Greatest Conservation Need (SGCN), and utilizing the full array of traditional conservation tools such as management (e.g. habitat manipulation, restoration (e.g. acquisition, fee-simple easements), landowner education and incentives.

**Conservation Opportunity Areas:** areas of land and water where the likelihood of successful conservation is strongest and the conservation needs of wildlife and their habitats would be best met.

**Conservation Partners:** The wildlife biologists, ecologists, sportsmen and other conservationists, non-governmental organizations, business leaders, colleges and universities and state and federal agencies representing more than 60 entities (table 1-1) that worked with the Vermont Fish & Wildlife Department to create Vermont's Comprehensive Wildlife Conservation Strategy. When implementation of the Action Plan begins, any and all individuals, organizations, agencies and other entities wishing to participate will be considered conservation partners.

**Conservation Reserve Program (CRP):** provides annual land rental payments up to 15 years and cost sharing assistance to install water quality enhancement practices on environmentally sensitive land.

**Conservation Reserve Enhancement Program (CREP):** State and Federal partnership allowing incentive payments to landowners who set aside environmentally sensitive land along streams or field boundaries.

**Common Species:** "Keeping Common Species Common" is a phrase Congress used to describe its goal for the SWG program and the Action Plan. Common in this situation refers to any species that is not on the federal Endangered Species List (Threaten or Endangered).

**Contiguous Forest:** An area of forested land with either no roads or low densities of class IV roads, and little or no human development (buildings, parking areas, lawns, gravel pits). Contiguous forest may have various age classes of forest cover and include other habitat types such as wetlands or grasslands that are part of the overall contiguous habitat complex.

**Corridor:** A route that permits the direct travel or spread of animals or plants from one area or region to another, either by the gradual spread of a species' population along the route or by the movement of individual animals, seeds, pollen, spores, or microbes.

**Cultural Habitat:** (sometimes referred to as anthropogenic habitat) communities and sites that are either created and/or maintained by human activities or are modified by human influence to such a degree
that the physical condition is substantially different from what existed prior to human influence (e.g. old mines, hayfields used by grassland birds, buildings and structures used by bats).

**Data Gap:** A clear data need identified in the Action Plan as important to the conservation of a species or habitat.

**Ecosystem:** A complex array of organisms, their natural environment, the interactions between them, and the ecological processes that sustain the system. Ecosystems can be defined at any scale, from rotting logs, to Lake Champlain, to the Green Mountains.

**Endangered Species:** A species in danger of becoming extinct that is protected by either the federal Endangered Species Act or the Vermont Endangered Species Act.

**Endemic species** Found only in a certain place. For the purposes of this document endemic refers to species found only in Vermont. There are no known endemic species in Vermont. The most likely possibilities are invertebrates.

**Exotic Invasive & Pest Species:** An invasive species is defined by the as a species that is 1) non-native (or alien) to the ecosystem under consideration and 2) whose introduction causes or is likely to cause economic or environmental harm or harm to human health.

**Environmental Quality Incentives Program (EQIP):** provides cost sharing payments to participants who install enduring conservation practices to help control soil erosion and improve water quality.

**Forest Cover Type:** A descriptive classification of forestland based on present occupancy of an area by tree species (Society of American Foresters).

**Game Species:** Wildlife species that are subject to legal hunting, fishing or harvesting.

**Habitat:** A place where a plant or animal lives. A place where an organism lives. Habitat is generally thought of in terms of single species such as bear or calypso orchid habitat.

**Herp:** an abbreviation for herptile, which includes both amphibian and reptile species.

**Herptile:** amphibian and reptile species

**Indicator species:** A species, or community whose presence in an area indicates the presence of certain environmental conditions.

**Indicators:** Indicators are measures that track inputs, outputs, and outcomes by stating them in specific and observable terms. They are also used to monitor natural resource conditions and the threats that can degrade natural ecosystems (e.g. the number lakes infested with Eurasian watermilfoil; the distribution of lakes infested with Eurasian watermilfoil # of boat checks conducted; % of boaters aware of exotic species laws)

**Landscape:** A heterogeneous area of land containing groups of natural communities and clusters of interacting ecosystems. These can be of widely varying scales, but normally include a range of elevations, bedrock, and soils.

**Life-history traits:** Examples include be species with low fecundity, that take a long time to reach sexual maturity, that take a long time between reproductive events (sturgeon, wood turtle)

**Limiting factor:** The factor that limits the growth, abundance, or distribution of a population of organisms or a habitat.

**Metadata:** Definitional information that provides information about or documentation of other data

**Metapopulation:** A small number of relatively isolated populations that may occasionally exchange individuals
**Mosaic:** A pattern of vegetation in which two or more different plant communities are interspersed in patches.

**Natural Community:** An interacting assemblage of plants and animals, their physical environment, and the natural processes that affect them.

**Neotropical Migrants:** Birds especially songbirds, that summer and breed in North America but migrate to the tropics for the winter. Neotropical refers to the region south of the Tropic of Cancer that includes southern Mexico, Central and South America, and the West Indies.

**Nongame Wildlife:** Wildlife species that are not subject to legal hunting, fishing or harvesting.

**Pathogen:** Any disease producing microorganism or material

**Problem:** A force causing a negative impact at the species, population, habitat and landscape levels (e.g., habitat conversion, pollution, illegal pet trade). A problem can also be the lack of information or a data gap vital to the successful management of a species. Because this report addresses an extremely broad range of problems affecting species and their habitats, the term "problem" may not always be the most appropriate term: threat, stress, stressor, issue, concern and limiting factor may at times be more accurate.

**Regulated Hunting/Fishing/Trapping:** The harvest of wildlife under regulations stipulating setting of seasons, time frame of lawful harvest, open and closed zones, methods of take, bag limits, possession limits, and reporting or tagging of species.

**Responsibility Species:** Species for which Vermont has a long-term stewardship responsibility because they are not doing well regionally, even if populations are stable in Vermont. E.g. bobolink

**SGCN:** see Species of Greatest Conservation Need

**Species of Greatest Conservation Need (SGCN):** According to federal legislation and guidance from the USFWS on the development of Comprehensive Wildlife Conservation Strategies, "each State will determine these species in the context of developing its [Wildlife Conservation Strategy]. These species must be fauna, and not flora, and may include aquatic species and invertebrates. A State's list of "species of the greatest conservation need" may include currently listed Federal and State wildlife species and other species of concern. We anticipate that the composition of this list will change over time as the status and conservation need of species changes within the State." The term Species of Greatest Conservation Need is not a statutory designation similar to the terms "endangered" or "threatened" codified by federal and state Endangered Species Acts.

**Take/Taking:** "Take" and "Taking" mean pursuing, shooting, hunting, killing, capturing, trapping, disturbing, harrying, worrying, or wounding snaring and netting fish, birds and quadrupeds and all lesser acts including placing, setting, drawing or using any net or other device commonly used to take fish or wild animals, whether they result in taking or not. It includes every attempt to take and every act of assistance to another person in taking or attempting to take fish or wild animals.

**Threatened Species:** Any species which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range that is protected by either the federal Endangered Species Act or the Vermont Endangered Species Act.

**Wildlife:** According to State Wildlife Grants legislation, wildlife is any species of wild, free-ranging fauna including fish, and invertebrates and also fauna in captive breeding programs the object of which is to reintroduce individuals of a depleted indigenous species in a previously occupied range.

**Wildlife Action Plan (Action Plan)** The Action Plan sets a plan of action for conserving Vermont's wildlife by addressing conservation issues, management needs, and priorities. It is intended to be used by anyone with an interest in wildlife conservation. It was developed under the working title of Comprehensive Wildlife Conservation Strategy (CWCS).
**Acronym Key**

This key includes many of the acronyms used in this document. Please let the authors know if additional entries are warranted. A full list of the Conservation Partners collaborating on the development of this report can be found in Chapter 1: Introduction.

**Common Name:** Common Loon  
**Scientific Name:** Gavia immer  
**Species Group:** Bird

### Conservation Assessment:

**Final Assessment:** High Priority  
**Global Rank:** G5  
**State Rank:** S2B, S4N  
**Global Trend:** Stable  
**State Trend:** Stable  
**Extirpated in VT?** No  
**Regionally Rare?** Yes

**Assessment Narrative:**
Officially designated as Endangered in VT in 1978, statewide population has steadily rebounded from a low of 8 nesting pairs in 1983 and 1984 to 43 pairs in 2004. Increases due in large part to concerted management; population unlikely to remain secure without sustained management and monitoring for foreseeable future. See: VT Loon Recovery Plan. Currently proposed for delisting from VT Endangered Species List.

**Distribution:**

**Natural History Elements:**
- **Home Range:** < 10 ha  
- **Migrant?** Yes  
  - **Within watershed:** Yes  
  - **Within biophysical region:** Yes  
  - **Within VT:** Yes  
  - **Within Region:** Yes  
  - **Within US:** Yes  
  - **Outside US:** No

**Distribution Summary:**
Breeding concentrated in northeastern and north-central VT, with 5 pairs in south-central and southern VT. Breeding possible, but unconfirmed on Lake Champlain.

**Habitat Description:**
Habitat Information is based on the following:
- **Limited Local Knowledge**  
- **Extensive Local Knowledge**  
- **Regional Literature**  
- **General Literature**

Freshwater lakes > 10 ha in size, particularly those containing small islands and coves.

</tbody>
</table>

#### Current Problems: (see Appendix C for definitions of problem categories)

**Habitat Problems:**

Conversion of Habitat

Habitat Alteration

*Description of habitat problem(s):* Lakeshore development and subsequent loss of shoreline habitat greatest single problem to breeding population. Recreational activities and direct human disturbance of nesting or nursery sites also a serious problem on more heavily used lakes.

**Non-Habitat Problems:**

Competition

Pollution

Trampling or Direct Impacts

*Description of non-habitat problem(s):* Mercury contamination has been shown to adversely affect loon reproduction and behavior in ME. Interference competition from extraterritorial loons has caused some territory and nest abandonments, as well as direct killing of chicks, in recent years.

### Research and Monitoring Needs

<table>
<thead>
<tr>
<th>Type</th>
<th>Need</th>
<th>Priority</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Research</td>
<td>Distribution and Abundance</td>
<td>Low</td>
<td>This is well known overall, due to sustained annual monitoring since 1978. Some smaller and more remote ponds need to be checked more regularly.</td>
</tr>
</tbody>
</table>
| Research   | Threats and Their Significance      | Medium   | 1) Extent of mercury contamination needs to be better documented. Collaborative research on extent and possible effects of mercury contamination in VT loons should be continued. A sampling scheme in VT should be developed in conjunction with an overall regional effort to monitor mercury in loons and other aquatic wildlife.  
2) Patterns of shoreline development and ownership of current and recent nest sites needs to be documented. |
| Monitoring | Population Change                   | High     | Sustained monitoring is crucial to documenting population trends                                                                                                                                              |
| Monitoring | Monitor Threats                     | Medium   | Monitoring of all limiting factors goes hand-in-hand with population monitoring and is critical to evaluate long-term viability and management needs of statewide population. Sick, weak, and dead loons should be collected and sent to wildlife health facilities for determination of cause of death, including interference competition from other loons (trauma), lead, and other contaminants. Annual summaries of known causes of deaths should be completed and disseminated. Results should be evaluated for management applications. |
**Common Name:** Common Loon  
**Scientific Name:** Gavia immer  
**Species Group:** Bird

### Species Strategies

(see Appendix B for additional habitat, community & landscape conservation summaries.)

<table>
<thead>
<tr>
<th>Strategy Type</th>
<th>Strategy Priority</th>
<th>Strategy Description</th>
<th>Performance Measure</th>
<th>Potential Partners</th>
<th>Potential Funding Sources</th>
</tr>
</thead>
<tbody>
<tr>
<td>Awareness Raising and</td>
<td>High</td>
<td>Continue concerted public education effort targeting landowners and lake users [for what purpose?]. Volunteers should receive expanded training, toward long-term goal of having loon monitoring and management be largely volunteer-based.</td>
<td>Public presentations, informational signs at VFWD lake access areas, media articles, and informal meetings with lakeshore residents and recreationists are all crucial to increased public awareness. Platforms and sign buoys must be used as necessary.</td>
<td>VFWD, VINS</td>
<td>State Nongame Fund</td>
</tr>
<tr>
<td>Communications</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Easements</td>
<td>High</td>
<td>Long-term protection of all current and recent (within past 5 years) loon nest sites should be secured through conservation easements and land acquisition.</td>
<td>Ownership of all current and recent nest sites should be documented. For those nest sites not currently protected, landowners should be contacted and protocols for securing protection should be developed.</td>
<td>VFWD, VINS, TNC, Lake Associations, Lake Associations, power companies</td>
<td>TNC</td>
</tr>
<tr>
<td>Species Restoration</td>
<td>High</td>
<td>A post-listing monitoring and management plan should be developed and implemented.</td>
<td>Plan should ensure annual monitoring for at least 5 years after post-listing; annual management should be continued as necessary; after 5 years, future needs should be evaluated. Annual LoonWatch should be continued indefinitely.</td>
<td>VFWD, VINS</td>
<td>VFWD, USFWS</td>

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Conversion of Habitat
- Habitat Alteration
- Invasion by Exotic Species

Description of habitat problem(s): Conversion of Habitat - loss of wetlands due to draining, filling for development and agriculture.
- Habitat Degradation - outdoor recreational activities disturb nesting.
- Invasion by exotic species - common reed and purple loosestrife compete with native vegetation for nesting and feeding sites.

Non-Habitat Problems:
- Harvest or Collection
- Trampling or Direct Impacts

Description of non-habitat problem(s): Harvest or Collection - sometimes mistakenly shot as waterfowl.
- Trampling or Direct Impacts - nests susceptible to damage by boating.
Common Name: Pied-billed Grebe  
Scientific Name: Podilymbus podiceps  
Species Group: Bird

Bibliography:

Common Name: American Bittern
Scientific Name: Botaurus lentiginosus
Species Group: Bird

Conservation Assessment:

Final Assessment: High Priority
Global Rank: G4
State Rank: S3B,S3N

Global Trend: Unknown
State Trend: Unknown

Extirpated in VT? No
Regionally Rare? No

Assessment Narrative:

The distribution and population status of this species of regional conservation concern are not well documented in VT. The Breeding Bird Survey indicates a 3.8% annual increase, but this is based on a small sample of routes and low abundance, so can not be considered reliable.

Listed as a Nongame Species of Management Concern by USFWS in 1982 and 1987, but populations are inadequately monitored overall, so actual conservation status not well known.

Distribution:

Natural History Elements:

Home Range: < 10 ha
Migrant? No

Within watershed
Within biophysical region
Within VT
Within Region
Within US ✓
Outside US ✓

Distribution Summary:

From first VT Breeding Bird Atlas, confirmed breeding in large wetland complexes in Champlain Valley, also in West Rutland Marsh, sites in lower Connecticut River Valley, and two sites in north-central VT. Probably breeds in other larger wetland complexes (e.g., Memphremagog) and scattered smaller wetlands throughout the state.

Habitat Description:

Habitat Information is based on the following:

Limited Local Knowledge ✓ Extensive Local Knowledge ☐ Regional Literature ✓ General Literature ✓

Primarily freshwater wetlands with tall, emergent vegetation. Inhabits wetlands of all sizes (0.1-1,000 ha), but more abundant on larger than smaller wetlands. Prefers impoundments and beaver-created wetlands to those of glacial origin.
Common Name: American Bittern
Scientific Name: Botaurus lentiginosus
Species Group: Bird

**General Habitat Preferences:**
- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements: Unknown
- Prefers large wetland complexes: ✓
- Prefers large expanses of grassland habitat: □
- Prefers habitat mosaics: □
- Prefers actively managed woodland: □
- Requires movement corridors: □
- Prefers large expanses of forest habitat: □

**Vegetation Categories Used:**
- Grasslands and Hedgerows
- Marshes and Sedge Meadows

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Alteration
- Invasion by Exotic Species

_A description of habitat problem(s):_ Loss or degradation of wetland habitats the primary problem to this species throughout its range. Changes in wetland isolation and water stabilization may erode habitat quality. Invasion of Phragmites and purple loosestrife a further problem to native wetland vegetation.

**Non-Habitat Problems:**
- Pollution

_A description of non-habitat problem(s):_ Chemical contamination and human disturbance are identified problems.
**American Bittern**

**Scientific Name:** Botaurus lentiginosus

**Species Group:** Bird

### Research and Monitoring Needs

<table>
<thead>
<tr>
<th>Type</th>
<th>Need</th>
<th>Priority</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Research</td>
<td>Distribution and Abundance</td>
<td>Medium</td>
<td>1) More robust data are needed on the statewide distribution and abundance of this species in wetlands of different sizes and vegetative composition. 2) A standardized, coordinated statewide survey of this and other wetland birds is needed to establish baseline information on distribution and abundance. An extensive, single-season survey could be followed by annual monitoring at a core number of wetlands. A volunteer-based survey that uses standardized, repeatable protocols could collect presence/absence and relative abundance data at a large number of wetland sites statewide. A core number (12-15) of sites could be annually monitored for long-term trends.</td>
</tr>
<tr>
<td>Research</td>
<td>Threats and Their Significance</td>
<td>Medium</td>

- **Global Trend:**  
- **State Rank:** S2B,S2N  
- **State Trend:** Unknown  
- **Exirpated in VT?** No  
- **Regionally Rare?** Yes

**Assessment Narrative:**

No state BBS data. BBS routes are not well-sited for monitoring marsh species.  
Status of species unknown in state; the species is regularly found in relatively few marshes in VT (Kibbe 1985).

**Distribution:**

**Natural History Elements:**

- **Home Range:** < 10 ha  
- **Migrant?** Yes  
- **Within watershed**  
- **Within biophysical region**  
- **Within VT**  
- **Within Region**  
- **Within US**  
- **Outside US**

**Distribution Summary:**

Data from Kibbe (1985).

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge ✔  
- Extensive Local Knowledge ✔  
- Regional Literature ✔  
- General Literature ✔

Freshwater and brackish marshes densely vegetated with emergent and aquatic vegetation, patches of open water and woody vegetation (Gibbs et al. 1992). Most abundant in Iowa marshes in years when open water and emergent vegetation were at a 1:1 ratio.
Common Name: Least Bittern  
Scientific Name: Ixobrychus exilis  
Species Group: Bird

### General Habitat Preferences:

- **Minimum Elevation (m):** -1  
- **Maximum Elevation (m):** -1  
- **Patch Size Requirements:** > 1 ha  
- Prefers large wetland complexes: ☐  
- Prefers large expanses of grassland habitat: ☐  
- Prefers habitat mosaics: ☐  
- Prefers developed landscapes: ☐  
- Prefers actively managed woodland: ☐  
- Requires movement corridors: ☐  
- Prefers large expanses of forest habitat: ☐

### Current Problems:

(see Appendix C for definitions of problem categories)

- **Habitat Problems:**  
  - Conversion of Habitat  
  - Habitat Alteration  
  - Invasion by Exotic Species  

  **Description of habitat problem(s):** Loss of wetlands will continue to limit the species. Invasion of wetlands by loosestrife and phragmites will degrade habitat quality. Agricultural and urban runoff could reduce water quality and prey populations.

  **Description of non-habitat problem(s):**

### Research and Monitoring Needs

<table>
<thead>
<tr>
<th>Type</th>
<th>Need</th>
<th>Priority</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Research</td>
<td>Habitat Requirements</td>
<td>Low</td>
<td>Information about the distribution of LEBI in VT is lacking. A statewide (perhaps one-time) survey of all potential wetlands would also yield valuable information for other wetland-dependent species (SORA, VIRA, COME, PBGR, AMBI, BLTE). Marshbird monitoring programs are limited in their spatial extent in VT. An extensive initial survey would provide baseline data for a long-term monitoring program that would lay the foundation for a more representative marshbird monitoring program.</td>
</tr>
<tr>
<td>Research</td>
<td>Basic Life History</td>
<td>Low</td>

### Bibliography:

Common Name: Great Blue Heron
Scientific Name: Ardea herodias
Species Group: Bird

Conservation Assessment:

Final Assessment: Medium Priority
Global Rank: G5
State Rank: S2S3B,S5N
Global Trend: Stable
State Trend: Stable
Exirpated in VT? No
Regionally Rare? No

Assessment Narrative:

Population currently stable with numbers increasing at largest colony site, Missisquoi National Wildlife Refuge.

Largest breeding colony (350 pairs) currently located at Missisquoi National Wildlife Refuge, second largest at Porters Bay on Lake Champlain (~100 pairs). Smaller colonies located throughout the state. Missisquoi colony stable until 2000 when 600 pair colony failed due to disturbance early in the season. Has recovered to approx. 350 pairs.

Distribution:

Natural History Elements:

Home Range: N/A
Migrant? Yes
Within watershed
Within biophysical region
Within VT
Within Region
Within US
Outside US

Distribution Summary:

Widely distributed with the largest colonies located in Champlain Valley. Smaller colonies located throughout state.

Habitat Description:

Habitat Information is based on the following:

Limited Local Knowledge ✓  Extensive Local Knowledge ✓  Regional Literature  General Literature

Colony nester, nesting in tall trees, usually in wooded swamps. Colony size ranges from a couple of pairs to more than 500 pairs. Inhabits marshes, swamps, streams and lakeshores.
Common Name: Great Blue Heron
Scientific Name: Ardea herodias
Species Group: Bird

**General Habitat Preferences:**
- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements: Unknown
- Prefers large wetland complexes: ☑
- Prefers large expanses of grassland habitat: □
- Prefers habitat mosaics: □
- Prefers developed landscapes: □
- Prefers actively managed woodland: □
- Requires movement corridors: □
- Prefers large expanses of forest habitat: □

**Vegetation Categories Used:**
(see Appendix B for habitat, community & landscape organization and conservation summaries)
- Floodplain Forests
- Hardwood Swamps
- Seeps and Pools
- Softwood Swamps

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Habitat Alteration
  - **Description of habitat problem(s):** Loss or degradation of nesting habitat at colony sites, especially larger colony sites directly impacts population

**Non-Habitat Problems:**
- Competition
- Predation or Herbivory
  - **Description of non-habitat problem(s):** Disturbance of nesting colony early in the season has lead to abandonment of nesting colonies. Increasing numbers of nesting Double-crested Cormorants at large colony sites results in competition for nesting space and habitat degradation
Common Name: **Great Blue Heron**  
Scientific Name: **Ardea herodias**  
Species Group: **Bird**

**Exirpated in VT?**

**Regionally Rare?**

**Assessment Narrative:**

Currently no documented nesting in Vermont.

Black-crowned Night-herons have been documented nesting on Lake Champlain, Vermont with the largest colony (30-50 pairs) having been on Young Island in Lake Champlain. Competition for nest sites and degredation of habitat by Double-crested Cormorants on Young Island resulted in the abandonment of that colony in the mid 1990's.

**Distribution:**

Has nested at 2 sites along Lake Champlain with the largest being Young Island on the northern part of the lake. Nesting has not been documented in the state since the mid 1990's.

**Natural History Elements:**

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Uses a variety of wetland habitats along the coast, in woodlands, boreal forest, mixed conifer-hardwoods, wherever there is water nearby. Nests in dense shrub vegetation usually near water but sometimes up to a mile or more away. Preferred wintering habitat includes brackish marshes bordering bays, estuaries, and agricultural areas, but also found on inland lakes, reservoirs, and marshes wherever ice-free conditions exist.
Common Name: American Black Duck
Scientific Name: Anas rubripes
Species Group: Bird

General Habitat Preferences:
- Minimum Elevation (m): 0
- Maximum Elevation (m): 0

**Current Problems:**  
(see Appendix C for definitions of problem categories)

**Habitat Problems:**
Conversion of Habitat

Habitat Alteration

*Description of habitat problem(s):* Conversion of wetlands to agriculture, wetland loss due to development

Habitat Degradation due to invasive plants such common reed, purple loosestrife.

Inadequate disturbance regime - early season mowing may disrupt nesting.

*Description of non-habitat problem(s):*
Common Name: **Blue-winged Teal**  
Scientific Name: **Anas discors**  
Species Group: **Bird**

<td>No</td>
<td></td>
</tr>
</tbody>
</table>

**Assessment Narrative:**

Species was nearly extirpated in Vermont due to habitat loss and the presence of DDT in the food chain. Since DDT was banned in 1972 and efforts were made to re-colonize areas with artificial nesting platforms, the osprey has made a dramatic come-back. The bird is well established around Lake Champlain and is slowly expanding in other areas of the state.

**Distribution:**

**Natural History Elements:**

- Softwood Swamps
- Upland Shores
- Wet Shores

### Current Problems: (see Appendix C for definitions of problem categories)

#### Habitat Problems:
- Conversion of Habitat
  - Description of habitat problem(s): Loss of large trees bordering lakes, ponds, rivers, wetlands due to poorly planned logging and development. Degradation of habitat due to water pollution and negative impacts to fisheries. Placement of roads and trails along water courses limits nesting habitat and increases mortality.

#### Non-Habitat Problems:
- Loss of Prey Base
- Pollution
- Reproductive Traits
- Trampling or Direct Impacts
  - Description of non-habitat problem(s): Pollution - sensitive to PCBs, pesticides, and heavy metals. Reproductive traits - does not reach breeding age until 4 or 5 years old. Relatively small clutches of 1-3 young. Loss of prey base - susceptible to changes in fisheries communities. Direct Impacts - susceptible to electrocution when nesting or foraging near power lines.

### Bibliography:

Common Name: Bald Eagle
Scientific Name: Haliaeetus leucocephalus
Species Group: Bird

Conservation Assessment:
Final Assessment: High Priority
Global Rank: G4
Global Trend: 
State Rank: SHB, S2N
State Trend: 
Extirpated in VT? Yes
Regionally Rare? Yes

Assessment Narrative:
No known breeding in Vermont. Translocation project in process, beginning in 2004.
State and Federally listed as endangered. No known breeding pairs in Vermont. Breeds in all adjacent states.

Distribution:

Natural History Elements:
Home Range: <1000 ha
Migrant? Yes
Within watershed
Within biophysical region
Within VT
Within Region
Within US
Outside US

Distribution Summary:
No documented breeding records as of 2004, although a few unsubstantiated reports from the Connecticut River in Caledonia County in recent years. Only known historical breeding record in Champlain Valley.

Habitat Description:
Habitat Information is based on the following:
Limited Local Knowledge Extensive Local Knowledge Regional Literature General Literature
Wintering: Large waterbodies with open water or good supply of carion (USFWS 1999).
Common Name: Bald Eagle
Scientific Name: Haliaeetus leucocephalus
Species Group: Bird

General Habitat Preferences:
- Minimum Elevation (m): 1
- Maximum Elevation (m): 0
- Patch Size Requirements: > 100 ha
- Prefers large wetland complexes: ☑
- Prefers large expanses of grassland habitat: □
- Prefers habitat mosaics: □
- Prefers developed landscapes: □
- Prefers actively managed woodland: □
- Requires movement corridors: □
- Prefers large expanses of forest habitat: □

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Climate Change
- Conversion of Habitat
- Habitat Alteration
- Impacts of Roads or Trails

Description of habitat problem(s): Habitat loss and human disturbance considered significant problems to breeding eagles. Roads and/or trails near nest site can be detrimental if human activity is not restricted (Buehler 2000). Climate change has the potential to reduce food supply.

Non-Habitat Problems:
- Disease
- Loss of Prey Base
- Pollution
- Trampling or Direct Impacts

Description of non-habitat problem(s): Eagles are most vulnerable to toxic substances - lead, mercury, pesticides, and other toxic chemicals. Also vulnerable to collisions with vehicles and power lines and possibly to disease (USFWS 1999, Buehler 2000) (West Nile Virus effects are yet unknown).
Common Name: Bald Eagle  
Scientific Name: Haliaeetus leucocephalus  
Species Group: Bird

Common Name: Bald Eagle
Scientific Name: Haliaeetus leucocephalus
Species Group: Bird

Bibliography:

USFWS. 1999. Endangered and threatened wildlife and plant; proposed rule to remove the bald eagle in the lower 48 states from the list of endangered and threatened wildlife. Federal Register 64(128): 36454-36464.
**Common Name:** Northern Harrier  
**Scientific Name:** Circus cyaneus  
**Species Group:** Bird

### Conservation Assessment:

- **Final Assessment:** High Priority  
- **Global Rank:** G5  
- **Global Trend:** Unknown  
- **State Rank:** S2B,S3S4N  
- **State Trend:** Unknown  
- **Extirpated in VT?** No  
- **Regionally Rare?** No

**Assessment Narrative:**

Detected on 5 BBS routes in VT (Sauer et al. 2004).

At risk of disappearing from the Northeast due to small breeding population size, there is suspected or documented decline of this species in some states, and declining trends in preferred early successional habitats. Population declines appear to be the result of habitat loss from reforestation, the filling of wetlands, and urban and industrial development in coastal areas. Recent trends in some states, however, are positive.

### Distribution:

**Natural History Elements:**

- **Home Range:** <1000 ha  
- **Migrant?** Yes  
- **Within watershed** No  
- **Within biophysical region** No  
- **Within VT** No  
- **Within Region** No  
- **Within US** Yes  
- **Outside US** Yes

**Distribution Summary:**

Data from Ellison (1985).

### Habitat Description:

Habitat Information is based on the following:

- **Limited Local Knowledge**  
- **Extensive Local Knowledge**  
- **Regional Literature**  
- **General Literature**

Open wetlands, marshy meadows, wet, lightly grazed pastures, old fields, marshes, upland prairies, mesic grasslands, drained marshlands, croplands, cold desert shrub-steppe, and riparian woodland. Densest populations typically associated with large tracts of undisturbed habitats dominated by thick vegetation (MacWhirter and Bildstein 1996).
### Northern Harrier

**Scientific Name:** Circus cyaneus  
**Common Name:** Northern Harrier  
**Species Group:** Bird

#### General Habitat Preferences:
- Minimum Elevation (m): 0  
- Maximum Elevation (m): 2400  
- Patch Size Requirements: Unknown  
- Prefers large wetland complexes: ☑  
- Prefers large expanses of grassland habitat: ☑  
- Prefers habitat mosaics: ☐  
- Prefers developed landscapes: ☐  
- Prefers actively managed woodland: ☐  
- Requires movement corridors: ☐  
- Prefers large expanses of forest habitat: ☐

#### Vegetation Categories Used:
- Grasslands and Hedgerows  
- Marshes and Sedge Meadows

#### Current Problems: *(see Appendix C for definitions of problem categories)*

##### Habitat Problems:
- Conversion of Habitat  
- Habitat Alteration  
- Habitat Fragmentation  
- Habitat Succession

**Description of habitat problem(s):** Major problem is likely early mowing of hayfields. Other problems include heavy grazing rotations in pastures, especially wet pastures and wetland drainage. Additionally, development hayfield abandonment (succession) and urban/suburban development are also problems.

##### Non-Habitat Problems:
- Loss of Prey Base

**Description of non-habitat problem(s):** Early mowing decreases rodent populations.
**Common Name:** Northern Harrier  
**Scientific Name:** Circus cyaneus  
**Species Group:** Bird

### Research and Monitoring Needs

<table>
<thead>
<tr>
<th>Type</th>
<th>Need</th>
<th>Priority</th>
<th>Description</th>

**Conservation Assessment:**

Final Assessment: Medium Priority  
Global Rank: G5  
Global Trend: Unknown  
State Rank: S2S3B  
State Trend: Unknown  
Exirpated in VT? No  
Regionally Rare? No

Assessment Narrative:

BBS Eastern Region trend, 1966-2003 = +8.09 (p=0.0000), however VT trend = -7.77 (p=0.14).

"Populations have stabilized or are increasing in some parts of [the continental] range, but the species has not fully recovered from the drastic decline of the period 1940-1970+ throughout much of the eastern part of the range; reasons for this lack of recovery are unknown; potentially limited by the use of organochlorine biocides in Central America and locally by habitat loss."(natureserve.org).

**Distribution:**

Biophysical Regions in Vermont

Natural History Elements:

- **Home Range:** > 1000 ha  
- **Migrant:** Yes  
- **Within watershed:** No  
- **Within biophysical region:** No  
- **Within VT:** No  
- **Within Region:** Yes  
- **Within US:** Yes  
- **Outside US:** Yes

Distribution Summary:

Distribution info from VT Breeding Bird Atlas - sightings reported in all biophysical regions except the Northeastern Highlands, but only 1 of 14 sightings was confirmed to be breeding (Laughlin & Kibbe 1985). Expert opinion is that Cooper's Hawks are now more common in VT than they were during the first atlas.

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Breeding & wintering: Mature stands in coniferous, hardwood, or mixed forest in semi-open landscape, including small woodlands and suburban forests. Tolerant of fragmentation and human disturbance (DeGraaf & Yamasaki 2001).
Common Name: Cooper's Hawk
Scientific Name: Accipiter cooperii
Species Group: Bird

General Habitat Preferences:
- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements: > 10 ha
- Prefers large wetland complexes: □

### Bibliography:

Northern Goshawk

Species Assessment Report

Common Name: Northern Goshawk
Scientific Name: Accipiter gentilis
Species Group: Bird

Conservation Assessment:

Final Assessment: Medium Priority
Global Rank: G5
State Rank: S3S4B
Global Trend: Unknown
State Trend: Unknown
Exirpated in VT? No
Regionally Rare? Yes

Assessment Narrative:

Relatively abundant and widespread, Holarctic; population trends are difficult to determine; no hard evidence of a significant decline in recent decades, but probably declining in some areas primarily as a result of habitat alteration (natureserve.org). Formerly nested principally in Canada, but expanded breeding range south into northeastern North America beginning around 1950 (Laughlin & Kibbe 1985).

Distribution:

Natural History Elements:

Home Range: <1000 ha
Migrant? Yes
Within watershed
Within biophysical region
Within VT
Within Region
Within US
Outside US

Distribution Summary:

Distribution info from VT Breeding Bird Atlas (Laughlin & Kibbe 1985). NOGOs found in all regions of the state, with 7 confirmed breeding pairs in the central and southeastern part of the state, and 1 in the lower Champlain Valley. Most sightings were in areas of medium - high elevation, with all but 1 in the Champlain Valley in the hilly areas on the periphery of the region.

Habitat Description:

Habitat Information is based on the following:

Limited Local Knowledge □ Extensive Local Knowledge □ Regional Literature ✔ General Literature ✔

Breeding: Forest interior habitats prefers mature forests with large trees and open understories. Found in all elevations up to treeline (DeGraff & Yamasaki 2001). Nests usually in bottom of the canopy of a large hardwood tree in the East (Laughlin & Kibbe 1985). In Minnesota, 81% of 46 goshawks nests were in aspen trees, generally located in mature (>50 years) early successional upland hardwood stands (aspen and paper birch forest types) (Boal et al. 2001). Prey is primarily small to medium birds, but will also feed on small mammals. Preferred feeding habitats are openings in forests (DeGraaf & Yamasaki 2001).
Common Name: Northern Goshawk
Scientific Name: Accipiter gentilis
Species Group: Bird

**General Habitat Preferences:**
- Minimum Elevation (m): 30
- Maximum Elevation (m): 760
- Patch Size Requirements: Unknown
- Prefers large wetland complexes: ☐
- Prefers large expanses of grassland habitat: ☐
- Prefers habitat mosaics: ☐
- Prefers actively managed woodland: ☐
- Requires movement corridors: ☐
- Prefers large expanses of forest habitat: ☑

**Vegetation Categories Used:**
(see Appendix B for habitat, community & landscape organization and conservation summaries)
- Early Succession Boreal Conifers
- Early Succession Boreal Hardwoods
- Early Succession Northern Hardwoods
- Early Succession Pine and Hemlock
- Early Succession Spruce-Fir
- Early Succession Upland Oak
- Northern Hardwood
- Oak-Pine Northern Hardwood
- Spruce Fir Northern Hardwood

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Fragmentation
- Impacts of Roads or Trails

*Description of habitat problem(s):* Loss of interior mature forest caused decline when Europeans settled New England. Does not nest in small forest tracks bounded by roads (DeGraaf & Yamasaki 2001).

**Non-Habitat Problems:**
- Pollution

*Description of non-habitat problem(s):* Highly sensitive to human presence (DeGraaf & Yamasaki 2001). Some sensitivity to pesticides/toxic checmicals.

- Lawns, Gardens, and Row Crops
- Mine
- Upland Shores

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Succession
  
  **Description of habitat problem(s):** Inappropriate development, poorly planned forest management and habitat changes on or near a cliff during the breeding season may disturb nesting peregrines and cause them to abandon their nest site. Any development on or near a cliff may be enough to cause a pair to abandon that nest site (USFWS 1991, Fowle et al. 2000).

**Non-Habitat Problems:**
- Loss of Prey Base
- Pollution
- Predation or Herbivory
- Trampling or Direct Impacts

  **Description of non-habitat problem(s):** Pesticides and other toxic chemicals have shown negative effects in the past, and some of these chemicals persist today (Fowle et al. 2000, USFWS, unpublished data). West Nile Virus may have an impact on the population in the future. Human disturbance on or near nesting cliffs is the greatest known problem to peregrines nesting in VT. Predation of young on the nest site has been an occasional problem in the past (Fowle et al. 2000).

Bibliography:

Spruce grouse (Falcipennis canadensis, formerly Dendragapus canadensis) inhabit the boreal forests of North America. Although considered common in Canada and in a few northern states, in Vermont the species is near the southern edge of its range. Historical accounts indicate the species was present in the northeastern counties of Orleans and Essex (Thompson 1853, Cutting 1884). Currently, breeding spruce grouse are restricted to a 62 km² (25 mi²) area of spruce-fir forest in northern Essex County (Royar and Alexander 1987). This breeding habitat is principally owned by the U.S. Fish and Wildlife Service (Nulhegan Division of the Silvio Conte Refuge) and the State of Vermont, Department of Fish and Wildlife (Wenlock Wildlife Management Area).

It is believed that between 150 and 300 adult birds occur in this population, and periodic surveys since 1990 show a stable if not slightly increasing population. Although the future of this population would seem secure given the interest of the two public owners in conserving wildlife (assuming that vegetation management will continue to maintain and improve habitat and that disturbance from the potential increase in recreationists to this area can be controlled) a stochastic event such as a widespread fire or disease outbreak could prove disastrous.

Full recovery of spruce grouse in Vermont will require the establishment of 2 additional sub-populations, most likely on the State Lands located in the southern Essex County towns of Victory and Granby, and in the northern Essex County town of Norton.

**Distribution Summary:**
Spruce grouse (Falcipennis canadensis, formerly Dendragapus canadensis) inhabit the boreal forests of North America. Although considered common in Canada and in a few northern states, in Vermont the species is near the southern edge of its range. Historical accounts indicate the species was present in the northeastern counties of Orleans and Essex (Thompson 1853, Cutting 1884). Currently, breeding spruce grouse are restricted to a 62 km² (25 mi²) area of spruce-fir forest in northern Essex.
Falciopennis canadensis  
Scientific Name: Spruce Grouse  
Species Group: Bird  

The spruce grouse is a bird of the boreal forest. Highest grouse densities (40-80 adults in summer/100 ha) are found in young dense jack pine (Pinus banksiana) stands, where live branches occur from 4-8 meters (13-26 ft) above ground (Szuba and Bendell 1983; Keppie 1995). Jack pine forests do not occur in Vermont, however, spruce-fir forests of similar structure provide suitable habitat throughout much of the species range. Keppie (1987) documented breeding densities of 9.8 - 21.9 adults/100 ha (0.25-0.55/ac) in a New Brunswick spruce-fir pine forest. Spruce (Picea spp.) is preferred over fir (Abies balsamea) because it develops and maintains better vertical stratification. A shrub layer of Vaccinium spp. or regenerating spruce-fir in low densities enhances habitat for spruce grouse (Robinson 1969). Larch (Larix laricina) in the overstory may provide a preferred fall food resource. Forest openings are important to female spruce grouse and their broods, as they provide greater abundance of accessible food resources for chicks than the dense forest (Allan 1985).

Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

The spruce grouse is a bird of the boreal forest. Highest grouse densities (40-80 adults in summer/100 ha) are found in young dense jack pine (Pinus banksiana) stands, where live branches occur from 4-8 meters (13-26 ft) above ground (Szuba and Bendell 1983; Keppie 1995). Jack pine forests do not occur in Vermont, however, spruce-fir forests of similar structure provide suitable habitat throughout much of the species range. Keppie (1987) documented breeding densities of 9.8 - 21.9 adults/100 ha (0.25-0.55/ac) in a New Brunswick spruce-fir pine forest. Spruce (Picea spp.) is preferred over fir (Abies balsamea) because it develops and maintains better vertical stratification. A shrub layer of Vaccinium spp. or regenerating spruce-fir in low densities enhances habitat for spruce grouse (Robinson 1969). Larch (Larix laricina) in the overstory may provide a preferred fall food resource. Forest openings are important to female spruce grouse and their broods, as they provide greater abundance of accessible food resources for chicks than the dense forest (Allan 1985).

General Habitat Preferences:

- Prefers large expanses of forest habitat: Yes

Vegetation Categories Used:

- Early Succession Boreal Conifers
- Early Succession Spruce-Fir
- Open Peatlands
- Softwood Swamps
- Spruce Fir Northern Hardwood

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:

- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Habitat Succession

Description of habitat problem(s): Two main causes of historic spruce grouse decline are habitat loss and human encroachment. As colonial settlements expanded from southern Vermont into northeastern Vermont forests, spruce fir forests were cleared and the relatively tame spruce grouse was undoubtedly taken for human consumption whenever the opportunity arose. As industrial timber companies were formed, vast
Common Name: Spruce Grouse  
Scientific Name: Falcipennis canadensis  
Species Group: Bird

Areas of virgin spruce fir forest were cut, and 19th century loggers may have taken spruce grouse to supplement their daily fare. By 1980 spruce grouse apparently remained only in the Nulhegan Basin, which at the time was experiencing heavy cutting of its mostly mature forests. With the dawn of the new millennium, much of Essex County forests are publicly owned or subject to conservation easements held by the State and/or private conservation organizations. As a result, conservation and sustained forestry goals across much of Essex County forestland will likely maintain if not increase available spruce grouse habitat. Increasing human development, however, will no doubt continue to encroach on some peripheral habitats, and the forecast increases in outdoor recreationists to Essex County could disrupt breeding activities and/or increase susceptibility to predation or adverse weather conditions (especially if pets accompany their owners on excursions through grouse habitats).

**Non-Habitat Problems:**

Harvest or Collection

Predation or Herbivory

**Description of non-habitat problem(s):** Predation is likely the most common cause of spruce grouse mortality (Boag and Schroeder 1992) although no predator seems to depend on spruce grouse as a large part of its diet (Robinson 1980). A major predator of spruce grouse eggs is the red squirrel (Tamiasciurus hudsonicus) (Boag et al 1984, Naylor and Bendell 1987). Other potential predators in Vermont are the northern goshawk (Accipiter gentilis), barred owl (Strix varia), northern raven (Corvus corax), red fox (Vulpes vulpes), coyote (Canis latrans), bobcat (Lynx rufus), black bear (Ursus americanus), striped skunk (Mephitis mephitis), fisher (Martes americana) and ermine (Mustela erminea). On Mount Desert Island, 7 of 19 radio transmitter-carrying adult females (37%) were predated between April and late August (Whitcomb et.al.1996). Predators identified were a Red-tailed Hawk (Buteo jamaicensis), red fox and an unidentified raptor. A study in Ontario of 67 spruce grouse nests found 55% were depredated by red squirrels, red fox, black bear and striped skunk (D’Eon 1997).

Another potential problem, especially in small patches that might hold dispersing grouse, is accidental shootings by ruffed grouse hunters. A grouse hunter, conditioned to shoot quickly at a flushing grouse, could easily mistake a flushed spruce grouse for a ruffed grouse. A few accidental shootings were documented during the 1980's in Ferdinand and Norton. The continuation of educational efforts aimed at grouse hunters in Essex County should help prevent this source of mortality from actually limiting the population.

<th>Global Rank: G5</th>
<th>Global Trend:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Medium Priority</td>
<td>S5B</td>
<td>Declining</td>
</tr>
</tbody>
</table>

**Assessment Narrative:**

While no trend data is collected in Vermont, habitat declines and trends reported from other states (MA drumming survey, NH regional biologist information, ME hunter reports) indicate a general decline in ruffed grouse populations across New England. While the potential exists for some of these declines to be related to ruffed grouse "cycles", these cycles have been shown to be less prevalent in the NE than in midwest and northern/subarctic regions.

Early successional habitat components required by ruffed grouse are declining on both a statewide and regional basis. Losses of acceptable habitat continue due to conversion to non-forest use. On areas which remain forested, stand maturation due to reductions in active forest management have substantially reduced habitat quality. Conservation efforts should focus on implementing a comprehensive program of habitat improvements on both public land and private land.

**Distribution:**

**Natural History Elements:**

- **Home Range:** < 100 ha
- **Migrant?** Yes
- **Within watershed** Yes
- **Within biophysical region** No
- **Within VT** No
- **Within Region** No
- **Within US** No
- **Outside US** No

**Distribution Summary:**

Distributed statewide where acceptable habitat components are present.

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Prefers mosaic of young and mid-aged hardwood and hardwood/conifer forests. Typically utilizes maturing forest habitats for nesting, sapling/pole stage hardwood forest habitats for breeding, and very young hardwood forest regeneration habitats for brood rearing. While species can utilize and survive within edge and other suboptimal habitats, larger patch sizes of required habitat.
components adjacent to one another usually result in greater productivity and survival.

**General Habitat Preferences:**

- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements: > 10 ha
- Prefers large wetland complexes: ☑️
- Prefers large expanses of grassland habitat: ☑️
- Prefers habitat mosaics: ☑️
- Prefers developed landscapes: ☑️
- Prefers actively managed woodland: ☑️
- Requires movement corridors: ☑️
- Prefers large expanses of forest habitat: ☑️

**Vegetation Categories Used:**

(see Appendix B for habitat, community & landscape organization and conservation summaries)

- Early Succession Boreal Conifers
- Early Succession Boreal Hardwoods
- Early Succession Northern Hardwoods
- Early Succession Other Types
- Early Succession Pine and Hemlock
- Early Succession Spruce-Fir
- Early Succession Upland Oak
- Floodplain Forests
- Grasslands and Hedgerows
- Hardwood Swamps
- Marshes and Sedge Meadows
- Northern Hardwood
- Oak-Pine Northern Hardwood
- Open Peatlands
- Seeps and Pools
- Shrub Swamps
- Softwood Swamps
- Spruce Fir Northern Hardwood
- Upland Shores
- Wet Shores

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Conversion of Habitat
- Habitat Fragmentation
- Habitat Succession
- Inadequate Disturbance Regime
- Invasion by Exotic Species

**Description of habitat problem(s):**

- permanent loss of forest habitat to non-forest uses;
- regional forest maturation resulting in suboptimal brood survival due to lack of protective cover and resulting increased predation;
- fragmentation of dense regeneration habitats by mature forest resulting in substantially
declining species productivity and significant mortality in localized, and sometimes large areas. Coupled with habitat loss to conversion of non-forest habitats, some ruffed grouse sub-populations have been extirpated in areas of former population abundance.

**Non-Habitat Problems:**

- Parasites
- Predation or Herbivory

*Description of non-habitat problem(s):* Herbivory by white-tailed deer can substantially limit necessary brood habitats in areas of high deer abundance, although this is essentially a manifestation of an ES habitat volume-related problem.

### Conservation Assessment:

**Final Assessment:** Medium Priority  
**Global Rank:** G5  
**Global Trend:** Unknown  
**State Rank:** S4S5N  
**State Trend:** Unknown  
**Extirpated in VT?** No  
**Regionally Rare?** Unknown

#### Assessment Narrative:

This species population is believed to be stable. Impacts to breeding areas (Canadian tundra, muskeg) include commercial development, extraction of earth resources, and oil and gas development. Wetlands along migration routes in VT may be jeopardized by development also. Pollutants and un-regulated hunting may be concerns on wintering grounds (S. America).

### Distribution:

#### Biophysical Regions in Vermont

#### Natural History Elements:

**Home Range:** Yes  
**Migrant?** Yes

#### Distribution Summary:

#### Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Nesting habitat occurs in Arctic within the tundra-boreal forest ecotone or transition zone. Uses shallow wetlands, muskeg I areas with abundant aquatic invertebrates. Migratory habitats include lake shores, river banks, and wetlands near agricultural area and early successional forests and shrub patches.
Common Name: Lesser Yellowlegs
Scientific Name: Tringa flavipes
Species Group: Bird

General Habitat Preferences:
- Minimum Elevation (m): 0
- Maximum Elevation (m): 0

Patch Size Requirements:
- Prefers large wetland complexes: □
- Prefers large expanses of grassland habitat: □

Bibliography:
Common Name: Upland Sandpiper
Scientific Name: Bartramia longicauda
Species Group: Bird

Conservation Assessment:

- **Final Assessment:** High Priority
- **Global Rank:** G5
- **State Rank:** S2S3B,S3N
- **Global Trend:** 
- **State Trend:** Declining
- **Extirpated in VT?** No
- **Regionally Rare?** No

**Assessment Narrative:**
Currently listed as Endangered in Vermont and proposed for Endangered Status. Regional status is as follows: CT-S1, MA-S1, NH-S1, RI –S1, NY-S3, ME-S3 (see appendix I for codes)

Upland Sandpiper numbers have dropped sharply in Vermont since the early 1990's. Habitat loss due to direct loss and agricultural intensification implicated in this decline.

Distribution:

**Natural History Elements:**
- **Home Range:** No
- **Migrant?** No
- **Within watershed** □
- **Within biophysical region** □
- **Within VT** □
- **Within Region** □
- **Within US** □
- **Outside US** □

**Distribution Summary:**
Currently found in the Champlain Valley with highest concentrations in Addison and Alburg.

**Known Watersheds**
- NA

**Habitat Description:**
Habitat Information is based on the following:
- Limited Local Knowledge □
- Extensive Local Knowledge □
- Regional Literature □
- General Literature □

Upland Sandpiper, a migrant wintering in South America, prefers large grassland areas (50-100 acres) with a mosaic of grassland habitat types for nesting and brood rearing (pasture, hayfields, etc).
Common Name: Upland Sandpiper  
Scientific Name: Bartramia longicauda  
Species Group: Bird

### Bibliography:

Rangewide declines in American woodcock have been tied to similar declines in habitat area and quality, and losses of these habitats appears to be accelerating. Existing, moist-soil early-successional hardwood habitat (especially alder and aspen-dominated sites), and open field components required by woodcock should be identified on both public and some conserved private land, and these habitats should be actively managed to prevent further losses or qualitative declines. Additional work should focus on identifying areas where active habitat management would re-establish quality regeneration and open field habitat components across all biophysical regions.

**Distribution:**

American woodcock are present statewide where acceptable habitat exists. During migration, woodcock numbers increase and birds can often be found in less optimal habitat. While distributed across all Vermont biophysical regions, the relative scarcity of critical habitat components within these polygons makes this distribution map somewhat a misleading gauge of habitat security.

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge✓
- Regional Literature✓
- General Literature✓

Prefers young hardwood, hardwood/conifer and alder forests proximate to open-field habitats in moist soil areas. Typically utilizes dense alder or aspen regeneration forest habitats for nesting, brood rearing and adult feeding, open field or forest openings > 1 ac. for breeding and roosting. While species can utilize and survive within moist soil forest edge and other suboptimal habitats, larger patch sizes of required habitat components are desired.

**Natural History Elements:**

- **Home Range:** < 100 ha
- **Migrant:** Yes
  - Within watershed □
  - Within biophysical region □
  - Within VT □
  - Within Region □
  - Within US ✓
  - Outside US ✓

**Distribution Summary:**

American woodcock are present statewide where acceptable habitat exists. During migration, woodcock numbers increase and birds can often be found in less optimal habitat. While distributed across all Vermont biophysical regions, the relative scarcity of critical habitat components within these polygons makes this distribution map somewhat a misleading gauge of habitat security.
Common Name: American Woodcock  
Scientific Name: Scolopax minor  
Species Group: Bird

adjacent to one another usually result in greater productivity and survival.

- Wet Shores

### Current Problems:  
(see Appendix C for definitions of problem categories)

#### Habitat Problems:
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Habitat Succession
- Inadequate Disturbance Regime

**Description of habitat problem(s):** Losses of moist-soil regeneration/successional habitats has been implicated in 30-yr population decline in both eastern and central flyways. Additional concerns regarding conversion to agriculture and non-forest cover of overwintering habitat in southern U.S. Fragmentation of both field habitats by reforestation and feeding/brood cover by succession has likely increased brood mortality during post-hatch brood movements to adequate rearing habitat.

#### Non-Habitat Problems:
- Pollution
- Predation or Herbivory
**Common Name:** American Woodcock
**Scientific Name:** Scolopax minor
**Species Group:** Bird

**Description of non-habitat problem(s):** Some anecdotal and emerging scientific data concerns regarding soil contaminants (primarily heavy metals) inducing adult mortality and compromising productivity.

### Bibliography:

Common Name: Common Tern
Scientific Name: Sterna hirundo
Species Group: Bird

Conservation Assessment:
Final Assessment: High Priority
Global Rank: G5
State Rank: S1S2B,S2N
Global Trend: Stable
State Trend: Stable
Extirpated in VT? No
Regionally Rare? No

Assessment Narrative:
VT state endangered since 1988

Common Tern populations in Vermont declined during the 1970's and 80's from about 300-400 breeding pairs to approx. 50 breeding pairs in 1988. Since then numbers have increased steadily due to monitoring and management efforts and protection of nesting islands. Breeding numbers still remain below those recommended for down-listing to Threatened in Vermont and monitoring and management efforts will need to continue to avoid a population decline in the future.

Distribution:

Natural History Elements:
Home Range: <1 ha
Migrant? Yes

Within watershed
Within biophysical region
Within VT
Within Region
Within US
Outside US

Distribution Summary:
Nests on 4-5 small islands in the NE arm of Lake Champlain. Can be observed throughout the northern part of the lake.

Known Watersheds
Lake Champlain Direct

Habitat Description:
Habitat Information is based on the following:
Limited Local Knowledge
Extensive Local Knowledge
Regional Literature
General Literature

Nests on isolated islands, beaches, dredge spoils and human made structures in areas with little to no vegetation.
Common Name: Common Tern
Scientific Name: Sterna hirundo
Species Group: Bird

General Habitat Preferences:
- Minimum Elevation (m): 94
- Maximum Elevation (m): 110
- Patch Size Requirements: None
- Prefers large wetland complexes: 
- Prefers large expanses of grassland habitat: 
- Prefers habitat mosaics: 
- Prefers developed landscapes: 
- Prefers actively managed woodland: 
- Requires movement corridors: 
- Prefers large expanses of forest habitat: 

Vegetation Categories Used:
(see Appendix B for habitat, community & landscape organization and conservation summaries)

Aquatic: Lake Champlain

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Habitat Alteration

Description of habitat problem(s): Traditional nesting islands currently protected for species. No direct habitat problems documented although habitat degradation due to future use of nesting and roosting Double-crested Cormorants possible.

Non-Habitat Problems:
- Competition
- Predation or Herbivory
- Trampling or Direct Impacts

Description of non-habitat problem(s): Predation by avian predators and ants, competition for nesting sites with Ring-billed gulls and Double-crested Cormorants and human disturbance are primary problems to this species.

Common Name: Common Tern
Scientific Name: Sterna hirundo
Species Group: Bird

Bibliography:
Black Tern populations have remained low but stable during the past decade. The number of nesting locations, however, has declined to just one, Missisquoi National Wildlife Refuge.

**Natural History Elements:**
- **Home Range:** < 10 ha
- **Migrant:** Yes
  - **Within watershed:** Yes
  - **Within biophysical region:** No
  - **Within VT:** No
  - **Within Region:** No
  - **Within US:** No
  - **Outside US:** No

**Distribution Summary:**
Black Terns are currently only found at one location, Missisquoi National Wildlife Refuge on northern Lake Champlain. Nesting occurred regularly in Lake Memphremagog South Bay throughout the 1990's.

**Habitat Description:**
Habitat Information is based on the following:
- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Nests in wetlands consisting of both emergent (cattails) and shrub (buttonbush) vegetation with adequate floating vegetation to build nests on.
## Black Tern

**Scientific Name:** *Chlidonias niger*

Distribution Summary:

Distributed statewide, although less common in northeastern quarter of the state.

Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge: ✓
- Extensive Local Knowledge: □
- Regional Literature: □
- General Literature: □

Brushy pastures, shrubby hedgerows at edges of fields, dry, open woods and groves (DeGraff and Rudis 1986). Prefers groves of trees, forest edges, and thickets; frequently associated with water. In NE. U.S.; usually found in edges and clearings of young deciduous-coniferous woods; abandoned farmland...brushy hillsides and pastures hawthorn thickets " (Hughes 2001).
Common Name: Black-billed Cuckoo
Scientific Name: Coccyzus erythropthalmus
Species Group: Bird

General Habitat Preferences:
- Minimum Elevation (m): 0
- Maximum Elevation (m): 610
- Patch Size Requirements: > 1 ha
- Prefers large wetland complexes: □
- Prefers large expanses of grassland habitat: □
- Prefers habitat mosaics: □
- Prefers developed landscapes: □
- Prefers actively managed woodland: □
- Requires movement corridors: □
- Prefers large expanses of forest habitat: □

Vegetation Categories Used:
- Early Succession Boreal Hardwoods
- Early Succession Northern Hardwoods
- Early Succession Pine and Hemlock
- Early Succession Spruce-Fir
- Early Succession Upland Oak
- Grasslands and Hedgerows
- Lawns, Gardens, and Row Crops
- Shrub Swamps

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Conversion of Habitat
- Habitat Fragmentation
- Habitat Succession
  Description of habitat problem(s): "Declines in some regions could be due in part to reversion of abandoned farmland to forests that are unsuitable (Erskine 1992). Other problems responsible for declines could be modification of habitat on wintering grounds, hazards during migration, and pesticide use." (Hughes 2001).

Non-Habitat Problems:
- Pollution
  Description of non-habitat problem(s): Black-billed cuckoos may be highly vulnerable to pesticides used on insect outbreaks, perhaps especially on winter range in South America.

Bibliography:

Common Name: Barn Owl  
Scientific Name: Tyto alba  
Species Group: Bird

**Conservation Assessment:**

**Final Assessment:** Medium Priority  
**Global Rank:** G5  
**State Rank:** S1B, S1N  
**Global Trend:**  
**State Trend:** Unknown  
**Extirpated in VT?** Unknown  
**Regionally Rare?** No

**Assessment Narrative:**

"The Barn Owl is on the northern edge of its range in Vermont, and was not known to nest in the state until the [original] Atlas Project survey" (Laughlin and Kibbe 1985). No confirmed nesting records since 1983.

**Distribution:**

![Biophysical Regions in Vermont](image)

**Natural History Elements:**

**Home Range:** Unknown  
**Migrant?** Yes  
**Within watershed** No  
**Within biophysical region** No  
**Within VT** Yes  
**Within Region** Yes  
**Within US** Yes  
**Outside US** Yes

**Distribution Summary:**

Records from VT Breeding Bird Atlas show 4 confirmed nestings in the Champlain Valley from 1976-1981. Only one pair was still breeding in 1983 (Laughlin & Kibbe 1985). There have been no recent records of nesting barn owls.

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge  
- Extensive Local Knowledge  
- Regional Literature  
- General Literature

Breeding: Semi-open low elevation habitats - agricultural areas, grasslands, pastures, etc., with old barn silos or abandoned structures for nest sites. Will nest in tree hollows, burrows, and nest boxes (DeGraaf & Yamasaki 2001).

Wintering: Needs protected roosting areas, as it is sensitive to extreme weather (Laughlin & Kibbe 1985).
Common Name: **Barn Owl**  
Scientific Name: **Tyto alba**  
Species Group: **Bird**

### General Habitat Preferences:
- Minimum Elevation (m): 1

Common Name: Short-eared Owl
Scientific Name: Asio flammeus
Species Group: Bird

Conservation Assessment:

Global Rank: G5
State Rank: S1B,S2N
Extirpated in VT? Unknown
Regionally Rare? Yes

Assessment Narrative:

Unknown breeding status in VT - regular winter sightings in Champlain Valley.

BBS data indicate significant long-term overall decline, although trend unknown for many areas. Decline likely attributed to habitat conversion of marshes, grasslands, and low-use pastures.

Distribution:

Natural History Elements:

Home Range: <1000 ha
Migrant? Yes

Within watershed □
Within biophysical region □
Within VT □
Within Region ✔
Within US ✔
Outside US □

Distribution Summary:

Distribution info from VT Breeding Bird Atlas (Laughlin & Kibbe 1985). Two confirmed nestings found in Champlain Valley. Other sightings in Northern Green Mts, and Southern & Northern VT Piedmont - all single sightings. Significant wintering concentrations have been seen in the Champlain Valley.

Habitat Description:

Habitat Information is based on the following:

Limited Local Knowledge □ Extensive Local Knowledge ✔ Regional Literature ✔ General Literature ✔

Breeding: Open land (marshlands & grasslands preferred), but will also use agricultural land and other open habitat.

Wintering: same as above with little/no snow cover (DeGraaf & Yamasaki 2001).

Conservation Assessment:
Final Assessment: High Priority
Global Rank: G5
State Rank: S2S3B
Global Trend: Declining
State Trend: Declining
Exirpated in VT? No
Regionally Rare? No

Assessment Narrative:
BBS trend for Eastern Region, 1996-2003 = -4.59% (p = 0.00000). Data set for Vermont too small for analysis.
Species declining due to lack of upland openings, clear-cuts and bare patches necessary for nesting. Additional evidence that non-selective pest control for mosquitoes has resulted in declining food resource availability (largely moths).

Distribution:

Natural History Elements:
Home Range: < 100 ha
Migrant? Yes
Within watershed
Within biophysical region
Within VT
Within Region
Within US
Outside US

Distribution Summary:

Habitat Description:
Habitat Information is based on the following:
Limited Local Knowledge
Extensive Local Knowledge
Regional Literature
General Literature

Prefers nesting/breeding habitats including dunes, beaches, logged or clearcut areas, open forests, rock outcrops, gravel outwashes and gravel on flat roofed buildings. Utilizes virtually all open habitats, above water and open woodlands, including urban and suburban areas, during crepuscular feeding and migration.
Common Name: Common Nighthawk  
Scientific Name: Chordeiles minor  
Species Group: Bird

**General Habitat Preferences:**
- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements: > 10 ha
- Prefers large wetland complexes: □
- Prefers large expanses of grassland habitat: □
- Prefers habitat mosaics: □
- Prefers developed landscapes: □
- Prefers actively managed woodland: □
- Requires movement corridors: □
- Prefers large expanses of forest habitat: □

**Vegetation Categories Used:**  
(see Appendix B for habitat, community & landscape organization and conservation summaries)

Biophysical Regions in Vermont

Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Dry open deciduous or open mixed forest with little or no underbrush or herbaceous layer on forest floor. In NY, prefers dry, low-elevation hardwood forests. Absent from heavily forested areas, and missing from many areas of dense, uninterrupted forest; however evidence suggests that small, isolated woodlots in agricultural areas provide poor habitat (Md. Data).

Species Group: Bird  

**Conservation Assessment:**

**Final Assessment:** Medium Priority  
**Global Rank:** G5  
**State Rank:** S5B  
**Global Trend:** Declining  
**State Trend:** Declining

**Exirpated in VT?** No  
**Regionally Rare?** No

**Assessment Narrative:**

Breeding Bird Survey data displays decreasing trend for northern Vermont and slight increase in population trend for southern Vt. Largest regional declines include the St. Lawrence River Plain and northern New England.

This species has declined in most states throughout its range. Once nested in old growth forests with scattered large hollow trees for roosting. Since settlement and industrialization, the species has shifted its habitat to mostly urban areas with large chimneys used for roosting and nesting, and agricultural areas where barns and silos provide similar roosting and nesting habitat. Reductions in sizes of chimneys due to change from coal burning to oil and electricity use have now further reduced this species population.

**Distribution:**

**Natural History Elements:**

**Distribution Summary:**

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Chimney swifts formerly nested and roosted in caves and large dead trees. As European settlement and development increased, the birds nested mainly in large, tall chimneys in urban and suburban areas. The conversion from heating with coal to oil and electricity in residential homes and industrial plants has reduced the size of chimneys making them less suitable as nest sites for chimney swifts. Some experts believe the birds may still nest in large snags in rural areas. Chimney swifts forage in a variety of habitats, but seem to prefer open areas over densely forested habitats.
Common Name: Chimney Swift  
Scientific Name: Chaetura pelagica

### Bibliography:

Black-backed Woodpecker

Scientific Name: Picoides arcticus
Species Group: Bird

Conservation Assessment:

Final Assessment: Medium Priority
Global Rank: G5
State Rank: S2B,S2N
Global Trend: Unknown
State Trend: Unknown
Exirpated in VT? No
Regionally Rare? Yes

Assessment Narrative:

Black-backed woodpeckers in Vermont are habitat specialists that depend on mature/overmature spruce-fir-tamarack forests for nesting and foraging. Trends in amount of required habitat are unknown. Conversion of substantial amount of potential habitat from intensively managed industrial forest land to public or private land w/easements over the past decade may lead to increased and/or stable amount of preferred habitats. Habitat losses may be caused by seasonal and/or permanent residential development, especially at shoreline sites, which may experience increase frequency in the coming decade in northeastern Vermont.

Vegetation Categories Used:
(see Appendix B for habitat, community & landscape organization and conservation summaries)

Other Cultural
Spruce Fir Northern Hardwood

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
Conversion of Habitat
Inadequate Disturbance Regime

Description of habitat problem(s): Species seems to require disturbances in coniferous forests. Beaver ponds, burns, clearcuts, or wind throws all appear to be appropriate. The species has a large territory size (10-20 ha), therefore there seems to be wide spacing between territories. Other problems are conversion to nonforest habitat, loss of wintering habitat, and decrease in prey species (summarized from Altman and Sallabanks 2000).

Description of non-habitat problem(s):

**Assessment Narrative:**

Populations have shown a nation-wide decline, especially since 1980.

The purple martin once lived along riparian, lake shoreline, and swamp edges. It is now almost completely found inhabiting areas close to human settlement. It originally nested in tree cavities but almost all nesting now occurs in bird houses erected by humans, except in western U.S. where some natural nesting still occurs.

**Distribution:**

**Distribution Summary:**

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Historically found along riparian areas, lake and pond shorelines, and edges of forest openings. Currently found almost exclusively around human settlements.
Common Name: Purple Martin  
Scientific Name: Progne subis  
Species Group: Bird

**General Habitat Preferences:**
- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements:
  - Prefers large wetland complexes: □
  - Prefers large expanses of grassland habitat: □
  - Prefers habitat mosaics: □
  - Prefers developed landscapes: □
  - Prefers actively managed woodland: □
  - Requires movement corridors: □
  - Prefers large expanses of forest habitat: □

**Vegetation Categories Used:**
- Aquatic: Man-Made Water Bodies
- Building or Structure
- Grasslands and Hedgerows
- Lawns, Gardens, and Row Crops

(see Appendix B for habitat, community & landscape organization and conservation summaries)

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Invasion by Exotic Species
  - Description of habitat problem(s): Competes for nest sites with introduced house sparrow and European starling.
- No Habitat Threats

**Non-Habitat Problems:**
- Competition
  - Description of non-habitat problem(s): Competes with introduced house sparrow and European starling for nest sites. Inadequate number of nest boxes erected to attract martins and support population viability. Nest boxes may not be maintained adequately by owners.

Conservation Assessment:
Final Assessment: Medium Priority

Global Rank: G5
Global Trend: Unknown
State Rank: S1S2B, S1S2N
State Trend: Unknown
Extripated in VT? No
Regionally Rare? Yes

Assessment Narrative:
PIF List (BCR 14 High Priority). Vt. SAG Species of Special Concern. S1S2B. No BBS data for VT.

BBS trend 1966-2002 increased (ns) both survey wide and in USFWS Region 5, but declined (ns) in New York. No BBS trend data for Vermont as the species is sparsely distributed in only one physiographic region. Increased softwood harvest in northeastern Vermont between 1978 to 1984 heightened concern for the gray jay's continued existence, and the SAG proposed it be listed as threatened, but the proposal was rejected. Public lands and conservation easements acquired over the last 2 decades in prime gray jay range, along with higher than expected densities found by Barnard in his ongoing field studies (begun in 1991) have reduced this concern.

Distribution:

Natural History Elements:
Home Range: < 100 ha
Migrant? No
Within watershed ✔
Within biophysical region ✔
Within VT ☐
Within Region ☐
Within US ☐
Outside US ☐

Distribution Summary:
Distribution limited to largest boreal forest patches of northeastern Vermont. Strongholds include the Victory, Nulhegan and Coaticook River Basins. Also occurs at high elevation coniferous forest.

Habitat Description:
Habitat Information is based on the following:
Limited Local Knowledge ✔ Extensive Local Knowledge ☐ Regional Literature ✔ General Literature ✔

Coniferous forests and nearby deciduous or mixed woodlands.
Common Name: Gray Jay  
Scientific Name: Perisoreus canadensis  
Species Group: Bird

**General Habitat Preferences:**
- **Minimum Elevation (m):** 300
- **Maximum Elevation (m):** 1000
- **Patch Size Requirements:** Unknown
- **Prefers large wetland complexes:** ☐
- **Prefers large expanses of grassland habitat:** ☐
- **Prefers habitat mosaics:** ☐
- **Prefers developed landscapes:** ☐
- ** Requires movement corridors:** ☑
- **Prefers large expanses of forest habitat:** ☑

**Vegetation Categories Used:**
- Early Succession Boreal Conifers
- Early Succession Spruce-Fir
- Softwood Swamps
- Spruce Fir Northern Hardwood

**Current Problems:** *(see Appendix C for definitions of problem categories)*

**Habitat Problems:**
- Habitat Alteration
- Habitat Fragmentation

*Description of habitat problem(s):* Gray jays utilize all seral stages of coniferous forests, readily occupy managed landscapes, and readily visit bird feeders or take handouts directly from humans. Conversion of coniferous forests in Vermont strongholds unlikely, however, smaller occupied patches (if they exist) could be degraded by residential or commercial development.

**Non-Habitat Problems:**
- Harvest or Collection

*Description of non-habitat problem(s):* Accidental capture by trappers has been reported in Ontario. Susceptibility to land trap losses depends on types of baits used (Strickland and Ouellet 1993).

**Assessment Narrative:**

Increasing long-term BBS population trend survey-wide (Sauer et al. 2004).

The sedge wren as a breeding species in the Northeast is considered to be in jeopardy. In nearly all the states where it occurs, it is state-listed as an endangered or threatened species. Populations have evidently undergone dramatic declines in the latter part of 20th century after a northern expansion in range which was probably due to the clearing of forests in the 1800s. The more recent shift in landscape from old fields and pasturelands to forests or development, and the draining, filling, and impounding of shallow wetland areas have reduced nesting habitat and continues at a rapid rate. Although habitat loss remains the major factor in population declines, it appears that sedge wren populations today remain well below the level that available habitats could support. Species rare and local in VT (Kibbe 1985). Breeding pairs that are present in one year are not necessarily present in subsequent years (Strong, personal observation).

**Distribution:**

The sedge wren is found in

Data from Kibbe (1985).

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge ✓
- Extensive Local Knowledge
- Regional Literature ✓
- General Literature ✓

Dense, tall growths of sedges and grasses in wet meadows, hayfields, retired croplands, upland margins of ponds and marshes, coastal marshes, and sphagnum bogs. Avoids short, sparse, or open vegetative cover, flooded areas, and wetlands dominated by cattails (Herkert et al. 2001).
Common Name: Sedge Wren
Scientific Name: Cistothorus platensis
Species Group: Bird

General Habitat Preferences:
- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements: Unknown
- Prefers large wetland complexes: ✔
- Prefers large expanses of grassland habitat: ✔
- Prefers habitat mosaics: □
- Prefers developed landscapes: □
- Prefers actively managed woodland: □
- Requires movement corridors: □
- Prefers large expanses of forest habitat: □

Vegetation Categories Used:
- Grasslands and Hedgerows
- Marshes and Sedge Meadows

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Conversion of Habitat
- Habitat Alteration
- Habitat Succession

Description of habitat problem(s): Early haying of grasslands perhaps not as critical as SEWR in VT may be second nesting attempts of birds breeding further north earlier in summer. Consequently, drainage ditches in wet hayfields and meadows may reduce habitat availability. Succession of grassland habitats and conversion of agricultural habitats to urban/suburban developments problematic. Habitat conversion is likely not as severe a problem as for other grassland species, as SEWR requires wet meadow habitat and at least to some degree protected through regulatory measures.

Description of non-habitat problem(s):
Common Name: Sedge Wren  
Scientific Name: Cistothorus platensis  
Species Group: Bird

Species Group: Bird

Conservation Assessment:

Final Assessment: Medium Priority
Global Rank: G5
Global Trend:
State Rank: S5B
State Trend: Declining
Exirpated in VT? No
Regionally Rare? No

Assessment Narrative:

Veery population in VT declined at an annual rate of -0.4% between 1966-2003, according to USGS Breeding Bird Survey data. This is slightly less than similar annual declines in NY (1.3%), NH (-1.6%), ME (-2.1%), and USFWS Region 5 (-1.1%). Continent wide, Veeries declined at a nonsignificant annual rate of -1.4% during this period.

A fairly common species in appropriate mesic, mid-successional hardwood forests. May not be adequately monitored in all habitat types that it occupies (e.g. floodplain forests). An important inhabitant of floodplain forests, should be considered a species to carefully watch for conservation.

Distribution:

**Conservation Assessment:**

**Final Assessment:** High Priority  
**Global Rank:** G4  
**State Rank:** S3B  
**Global Trend:** Unknown  
**State Trend:** Unknown  
**Extirpated in VT?** No  
**Regionally Rare?** Yes

**Assessment Narrative:**

Species extensively studied by VINS since 1992, but no baseline data before that, so population trends still poorly known. Recent data from Mountain Birdwatch project indicate that species experienced an annual regionwide decline of 9.1% from 2001-2004.

A habitat specialist whose overall population trends and abundance are not well known. Conservation limiting factors on both breeding and wintering grounds, combined with rarity and occupancy of naturally fragmented habitats, place the species at conservation risk. A high priority for attention in VT.

**Distribution:**

![Biophysical Regions in Vermont](image)

**Natural History Elements:**

- **Home Range:** < 10 ha  
- **Migrant?** Yes  
- **Within watershed**  
- **Within biophysical region**  
- **Within VT**  
- **Within Region**  
- **Within US**  
- **Outside US**

**Distribution Summary:**

Distributed throughout high elevation montane forests of VT

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

montane fir-dominated forest
Common Name: Bicknell's Thrush
Scientific Name: Catharus bicknelli
Species Group: Bird

General Habitat Preferences:
- Minimum Elevation (m): 850
- Maximum Elevation (m): 1250
- Patch Size Requirements: > 10 ha
- Prefers large wetland complexes: 
- Prefers large expanses of grassland habitat: 
- Prefers habitat mosaics: 
- Prefers developed landscapes: 
- Prefers actively managed woodland: 
- Requires movement corridors: 
- Prefers large expanses of forest habitat: 

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Climate Change
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Impacts of Roads or Trails

Description of habitat problem(s): The primary problems in Vermont and the Northeast (there are other, likely more significant problems on the species' Caribbean wintering grounds) are degradation and fragmentation of montane forests. Atmospheric pollution may be affecting forest health, and climate change could profoundly impact long-term viability of montane balsam fir forests. Immediate problems include loss and fragmentation of habitat from ski area development, communications tower development, and wind turbine development.

Non-Habitat Problems:
- Pollution

Description of non-habitat problem(s): Mercury contamination may be a problem, as research has shown significantly higher atmospheric deposition rates in montane forests than in surrounding low elevation habitats. Recent research has indicated that Hg levels in adult BITH increase with age.

Vegetation Categories Used:
(see Appendix B for habitat, community & landscape organization and conservation summaries)

<td>Research</td>
<td>Basic Life History</td>
<td>Medium</td>
<td>Much basic life history is known, but some aspects of ecology and demography need further study</td>
</tr>
<tr>
<td>Research</td>
<td>Distribution and Abundance</td>
<td>Medium</td>
<td>Distribution is well-documented, but better information is needed on abundance and population ecology in different subhabitat types.</td>
</tr>
<tr>
<td>Research</td>
<td>Threats and Their Significance</td>
<td>Medium</td>
<td>1) Expand studies of mercury contamination in BITH and synergistic effects with other environmental stressors (such as calcium depletion); evaluate effects on reproductive success, behavior, survivorship. Design and implement expanded research program on multiple peaks (at least Stratton, Mansfield, and East Mt) 2) It is not known how developments affect local breeding populations</td>
</tr>
<tr>
<td>Research</td>
<td>Population Genetics</td>
<td>High</td>
<td>Knowledge of natal dispersal and migratory connectivity could help elucidate population structure and guide conservation planning</td>
</tr>
<tr>
<td>Research</td>
<td>Taxonomy</td>
<td>Low</td>
<td>Taxonomy, while still debatable to some, has been resolved and is not crucial to conservation</td>
</tr>
<tr>
<td>Research</td>
<td>Other Research</td>
<td>High</td>
<td>1) Conduct research that will enable robust predictions of breeding densities in different sub-habitat types, which can be extrapolated across VT and entire breeding range to derive population estimates. Design specific studies that will quantify BITH breeding densities, correlate density measures with GIS habitat data to estimate overall population numbers in different montane forest sub-habitat types. Use data to generate overall population estimates. 2) There are needs for additional research on the species' wintering grounds</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Population Change</td>
<td>High</td>
<td>Mountain Birdwatch is a critical, ongoing program to monitor population trends</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Habitat Change</td>
<td>High</td>
<td>Mountain Birdwatch will collect habitat information with bird population data, as a means to evaluate local changes that may be occurring. Landscape level monitoring of montane forest habitats is essential.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Range Shifts</td>
<td>High</td>
<td>Ongoing monitoring through Mountain Birdwatch will help assess distributional changes, as will programs underway in Quebec and Canadian Maritime provinces, where the species also breeds.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Monitor Threats</td>
<td>High</td>
<td>Landscape level studies of the impacts of development on montane forest species will be the only means to document changes that occur. The current strategy of reacting to site-specific projects (e.g. East Mountain wind farm) is unlikely to provide rigorous information that can be applied across the species' range.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Other Monitoring Needs</td>
<td>High</td>
<td>Monitoring must be continued on the species' winter range.</td>
</tr>
</tbody>
</table>

**Regionally Rare?** No  

**Assessment Narrative:**

Wood Thrush experienced a nonsignificant 2.1% annual decline in VT between 1966-2003, according to USGS Breeding Bird Survey data. The species is declining at similar rates in NH, ME, MA, and NY and throughout USFWS Region 5.

A common but declining breeding species of northern hardwoods forests, in many ways an "umbrella" species that merits focused conservation attention in VT. Its decline may be due in part to maturation of n. hardwoods forests, suggesting that targeted management might help stabilize or reverse declines. Factors on the species' Central American wintering grounds may also be involved in its declining populations.

**Distribution:**

![Biophysical Regions in Vermont](image)

**Natural History Elements:**

- **Home Range:** < 10 ha
- **Migrant?** Yes
- **Within watershed** ☐
- **Within biophysical region** ☐

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Fragmentation

**Description of habitat problem(s):** Forest fragmentation may introduce nest predators and cowbirds that lower reproductive success, especially in smaller, isolated patches

**Non-Habitat Problems:**
- Pollution

**Description of non-habitat problem(s):** Acidification of northern hardwoods forests and consequent calcium depletion may affect population ecology of this species

Common Name: Brown Thrasher
Scientific Name: Toxostoma rufum
Species Group: Bird

Conservation Assessment:

Final Assessment: Medium Priority
Global Rank: G5
State Rank: S5B
Global Trend: Declining
State Trend: Declining
Exirpated in VT? No
Regionally Rare? No

Assessment Narrative:

BBS trend 1966-2003 for VT was -1.37 (p = 0.25).
Species declining along with shrub dominated and successional habitats throughout the East as forests mature and suitable habitat is converted to non-forest/non-habitat use.

Distribution:

Natural History Elements:

Home Range: < 10 ha
Migrant? Yes
Within watershed
Within biophysical region
Within VT
Within Region
Within US
Outside US

Distribution Summary:
Statewide

Habitat Description:

Habitat Information is based on the following:
Limited Local Knowledge
Extensive Local Knowledge
Regional Literature
General Literature

Thicket/shrub complexes; hedgerows and early successional habitat w/ high stem densities coupled with low (10%-30%) canopy coverage.
Common Name: **Brown Thrasher**  
Scientific Name: **Toxostoma rufum**  
Species Group: **Bird**

**General Habitat Preferences:**
- Minimum Elevation (m): 0
- Maximum Elevation (m): 520
- Patch Size Requirements: > 1 ha
- Prefers large wetland complexes: □
- Prefers large expanses of grassland habitat: □
- Prefers habitat mosaics: □
- Prefers developed landscapes: □
- Prefers actively managed woodland: □
- Requires movement corridors: □
- Prefers large expanses of forest habitat: □

#### Bibliography:

Common Name: Blue-winged Warbler  
Scientific Name: Vermivora pinus  
Species Group: Bird

Conservation Assessment:

Final Assessment: Medium Priority  
Global Rank: G5  
Global Trend: 
State Rank: S2S3B  
State Trend: Declining  
Exirpated in VT? No  
Regionally Rare? No

Assessment Narrative:

Survey-wide, a non-significant (-0.6%) population decline. In Vermont, data are limited, but the species shows a large population increase, likely due to recent colonization of VT (Sauer et al. 2004).

RE: responsibility species: Rosenberg tier 1. Species will most likely be limited in VT as a result of forest succession and development.

Distribution:

Natural History Elements:

Home Range: < 10 ha
Migrant? Yes
Within watershed ☐
Within biophysical region ☐
Within VT ☐
Within Region ☐
Within US ☐
Outside US √

Distribution Summary:

Data from Clark (1985). Likely occurs in other regions in migration.

Habitat Description:

Habitat Information is based on the following:

Limited Local Knowledge ☑  Extensive Local Knowledge ☐  Regional Literature ☑  General Literature ☑

"Nests in brushy growth near the borders of swamps or streams, forest edges, abandoned fields and pastures, thickets, and second-growth woods. Prefers brushy old pastures and old fields with saplings < 3 m tall" (DeGraaf and Yamasaki 2001). Tends to use drier habitats than GWWA."
Common Name: Blue-winged Warbler
Scientific Name: Vermivora pinus
Species Group: Bird

General Habitat Preferences:
- Minimum Elevation (m): 0
- Maximum Elevation (m): 360
- Patch Size Requirements: None
- Prefers large wetland complexes: [ ]
- Prefers large expanses of grassland habitat: [ ]
- Prefers habitat mosaics: [ ]
- Prefers developed landscapes: [ ]
- Prefers actively managed woodland: [ ]
- Requires movement corridors: [ ]
- Prefers large expanses of forest habitat: [ ]

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Conversion of Habitat
- Habitat Alteration
- Habitat Succession

Description of habitat problem(s): Succession of old field to forest, loss of habitat to development, and fragmentation and BHCO parasitism major problems.

Description of non-habitat problem(s): Although hybridizes extensively with GWWA, introgressive hybridization appears to be asymmetric with BWWA gene pool remaining largely "pure" (Gill et al. 2001). Competition between BWWA and GWWA appears to be leading to continual northward shift in the range of GWWA. Colonization of GWWA breeding sites by BWWA leads to extirpation of GWWA within 50 years.

Vegetation Categories Used:
- Early Succession Northern Hardwoods
- Early Succession Pine and Hemlock
- Grasslands and Hedgerows

Vegetation Categories Used:
(see Appendix B for habitat, community & landscape organization and conservation summaries)

### Bibliography:

**Common Name:** Black-throated Blue Warbler  
**Scientific Name:** Dendroica caerulescens  
**Species Group:** Bird

### Conservation Assessment:

**Final Assessment:** Medium Priority  
**Global Rank:** G5  
**State Rank:** S5B  
**Extirpated in VT?** No  
**Regionally Rare?** No

### Assessment Narrative:

BBS survey trends variable by time period. Survey-wide, non-significant positive long-term trend, but significant decrease (-3%) 1666-1979 and significant increase (2%) 1980-2003. Interestingly, VT trends are opposite. Recent and long-term trends non-significant, but a significant (5.7%) increase 1966-1979 (Sauer et al. 2004). PIF continental objective is stability (1.0) and the step-down target for Vermont is 57,000 breeding individuals.

Population likely secure. Primary breeding ground limiting factors result from consequences of fragmentation (by permanent land use changes) on reproductive success. Because winter range is restricted to the Caribbean, there is some concern over the effects of deforestation on these islands, particularly the Greater Antilles.

### Distribution:

#### Natural History Elements:

- **Home Range:** < 10 ha  
- **Migrant?** Yes

  - **Within biophysical region** ☐  
  - **Within VT** ☐  
  - **Within Region** ☐  
  - **Within US** ☐  
  - **Outside US** ✓

**Distribution Summary:**

From Kibbe (1985).

### Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge ☐  
- Extensive Local Knowledge ✓  
- Regional Literature ✓  
- General Literature ✓

Large, continuous tracts of undisturbed deciduous or mixed deciduous/coniferous forests, often in hilly or mountainous terrain (Holmes 1994). "Uneven aged timber harvest methods such as selection or group cuts can effectively mimic the natural disturbance regime and seem to be compatible with Black-throated Blue Warbler conservation" (Burdett and Niemi 2003).
Common Name: Black-throated Blue Warbler  
Scientific Name: *Dendroica caerulescens*  
Species Group: Bird

### General Habitat Preferences:
- **Minimum Elevation (m):** 300
- **Maximum Elevation (m):** 1600
- **Patch Size Requirements:** > 100 ha
- Prefers large wetland complexes: ☐
- Prefers large expanses of grassland habitat: ☐
- Prefers habitat mosaics: ☐
- Prefers actively managed woodland: ☐
- Requires movement corridors: ☐
- Prefers large expanses of forest habitat: ☑

### Current Problems: *(see Appendix C for definitions of problem categories)*

#### Habitat Problems:
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation

**Description of habitat problem(s):** Productivity and density decrease in forest fragments. Susceptible to parasitism by Brown-headed Cowbirds in these forests when located in predominately agricultural landscapes. Habitat conversion through development or habitat alteration from clearcutting can limit species. Conversely, as forest regenerates from abandonment of agricultural lands, additional habitat will become available through succession.

**Description of non-habitat problem(s):**

### Vegetation Categories Used:

### Research and Monitoring Needs

<table>
<thead>
<tr>
<th>Type</th>
<th>Need</th>
<th>Priority</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Research</td>
<td>Distribution and Abundance</td>
<td>Medium</td>
<td>1) Compare changes in population trends across BBS routes in areas with different land use patterns. 2) More information is needed on distribution and overwinter survival in disturbed habitats on wintering grounds.</td>
</tr>
<tr>
<td>Research</td>
<td>Threats and Their Significance</td>
<td>High</td>
<td>Effects of fragmentation on breeding season productivity, particularly the effects of predation and cowbird parasitism should be further researched. Landscapes dominated by contiguous forests have not consistently shown increased predation trends associated with relatively temporary disturbances, such as timber harvests; “It is critical to better comprehend the complex relationships that exist between nest predation, habitat fragmentation, and landscape context.” (Burdett and Niemi 2003).</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Population Change</td>
<td>Medium</td>
<td>A better assessment of population trends across a variety of landscape types is needed.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Habitat Change</td>
<td>High</td>
<td>1) Better information on land use change in Vermont would help concentrate development in areas that would be less likely to affect forest interior species. Trends in rate of forest loss and fragmentation across range should be investigated. 2) Continue to monitor populations at Hubbard Brook Experimental Forest (unfragmented), uneven-aged-managed forests, and forest fragments in Vermont to better assess the effect of patch size and management on population trends using a source-sink framework.</td>
</tr>
</tbody>
</table>

Common Name: Black-throated Blue Warbler  
Scientific Name: Dendroica caerulescens  
Species Group: Bird  

Bibliography:  
Burdett, C.L. and G.J. Niemi. 2003. Conservation assessment for Black-throated Blue Warbler (Dendroica caerulescens) USDA Forest Service, Eastern Region. Natural Resources Research Institute, Univ. of Minnesota, Duluth, Minnesota, USA.

Common Name: **Prairie Warbler**  
Scientific Name: **Dendroica discolor**  
Species Group: **Bird**

**Conservation Assessment:**

- **Final Assessment:** Medium Priority  
- **Global Rank:** G5  
- **Global Trend:** Declining  
- **State Rank:** S3B  
- **State Trend:** Declining  
- **Extirpated in VT?** No  
- **Regionally Rare?** Yes

**Assessment Narrative:**

BBS trend for eastern region, 1966-2003 = -1.88 (p= 0.00001)

Very significant declines in the US per BBS data 1966 -1993; less significant decline 1984-1993. Distribution during first Vermont Bird Atlas was limited to the eastern foothills (Clark 1985).

**Distribution:**

![Biophysical Regions in Vermont](image)

**Natural History Elements:**

- **Home Range:** <1 ha  
- **Migrant?** Yes  
- **Within watershed**  
- **Within biophysical region**

- **Within US**  
- **Outside US**

**Distribution Summary:**

Rare breeded in southern Vermont.

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge  
- Extensive Local Knowledge  
- Regional Literature

Breeding habitat of early successional hardwood forest regeneration, old field, shrub/dune, upland shrub habitats; prefers open canopy (however uses closed canopy palustrine forest in Mid-Atlantic breeding areas). Utilizes Christmas tree farms and gravel pit/mine shrub habitats.
Prairie Warbler

Dendroica discolor

Bird

**Distribution Summary:**

First breeding confirmation was near Sable Mountain, Granby (1980). Subsequently confirmed nesting at Wenlock Wildlife Management Area, Ferdinand (1987) and Brighton State Park, Brighton (1995).

### Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Mainly breeds in dense, boreal forests of mature spruce and fir; also inhabits old mixed-wood stands and prefers moist, swampy areas to dry, upland locations. (Mayasich and Niemi 2002). Dramatic increases reported in response to outbreaks of spruce budworm (Choristoneaura fumiferana).
Common Name: **Bay-breasted Warbler**  
Scientific Name: **Dendroica castanea**  
Species Group: **Bird**

**General Habitat Preferences:**
- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements: Unknown
- Prefers large wetland complexes: 
- Prefers large expanses of grassland habitat: 
- Prefers habitat mosaics: 
- Prefers developed landscapes: 
- Prefers actively managed woodland: 
- Requires movement corridors: 
- Prefers large expanses of forest habitat: 

**Vegetation Categories Used:**
(see Appendix B for habitat, community & landscape organization and conservation summaries)
- Early Succession Boreal Conifers
- Early Succession Spruce-Fir
- Softwood Swamps
- Spruce Fir Northern Hardwood

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Fragmentation

**Description of habitat problem(s):** Loss and fragmentation of late successional, lowland spruce-fir forest; management practices that favor short-cutting cycles preventing establishment of late successional forests

**Description of non-habitat problem(s):**  Possible impacts from aerial spraying for spruce budworm (declines following application of organophosphate insecticides documented in New Brunswick in 1970s)
Common Name: Bay-breasted Warbler
Scientific Name: Dendroica castanea
Species Group: Bird

### Research and Monitoring Needs

#### Research and Monitoring Needs

<table>
<thead>
<tr>
<th>Type</th>
<th>Need</th>
<th>Priority</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Research</td>
<td>Habitat Requirements</td>
<td>Medium</td>
<td>Habitat needs reasonably well known, although population structure in different subhabitat types (krummholz, regenerating chronically disturbed forests, taller stature and more open forests, transitional spruce-fir-birch forests) not well known.</td>
</tr>
<tr>
<td>Research</td>
<td>Basic Life History</td>
<td>High</td>
<td>Demographics and breeding success need more study, especially in different subhabitat types.</td>
</tr>
<tr>
<td>Research</td>
<td>Distribution and Abundance</td>
<td>Medium</td>
<td>Fairly well known, although relative abundance in different subhabitat types needs to be better quantified. Conduct research that will enable robust predictions of breeding densities in different sub-habitat types, which can be extrapolated across breeding range to derive population estimates.</td>
</tr>
<tr>
<td>Research</td>
<td>Threats and Their Significance</td>
<td>High</td>
<td>1) Species’ susceptibility and response to habitat fragmentation and conversion from development (ski area, wind turbines, telecommunications facilities) needs to be better understood. Evaluate impacts of human development (ski area expansion/construction, wind power, telecommunications facility) on Bicknell’s Thrush and montane forest habitat, and use results to guide future development. 2) Impacts of atmospheric pollutants (e.g. mercury) and possible role of calcium depletion should be studied</td>
</tr>
<tr>
<td>Research</td>
<td>Population Genetics</td>
<td>Low</td>
<td>Genetic structure of breeding populations in Northeast, and relation to core breeding populations in Canada interesting, but probably not crucial for conservation</td>
</tr>
<tr>
<td>Research</td>
<td>Taxonomy</td>
<td>Low</td>
<td>Same as above</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Population Change</td>
<td>High</td>
<td>Species poorly monitored by traditional methods like BBS. VINS Mountain Birdwatch program monitors adequately, but must be maintained for long-term. Very important to monitor this species as an avian indicator of montane forests. Continue long-term monitoring at a minimum of 15-20 sites in VT to document population trends.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Habitat Change</td>
<td>High</td>
<td>Important to document habitat changes in concert with population changes</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Range Shifts</td>
<td>Medium</td>
<td>This should be covered by a regional monitoring program (i.e. Mountain Birdwatch)</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Monitor Threats</td>
<td>Medium</td>
<td>Important to monitor limiting factors like development, atmospheric pollution, mercury burdens</td>
</tr>
</tbody>

<td></td>
</tr>
<tr>
<td>Habitat Restoration</td>
<td>Medium</td>
<td>Identify 10-15 core breeding sites and ensure that a long-term protection plan exists for each.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(see Appendix B for additional habitat, community & landscape conservation summaries.)

**Bibliography:**

Historic population at the mouth of the Lamoille River appears to be extirpated. In 2002-2004, singing males have been located in Niquette Bay State Park, Highgate, and near Colchester Pond. More populations may be discovered as Vermont's forests continue to mature (and the second breeding bird atlas is completed), however declines throughout its range suggest that this species will never be common in Vermont. Preliminary survey data from the wintering range suggest that it can be found in a diversity of forest types in Columbia, Venezuela, Ecuador, and Peru (Hamel 2000).

As summarized by Hamel (2000), this species requires a closed canopy, presence of scattered tall, old growth canopy trees, and distinct layering of foliage from ground cover to canopy. Area sensitivity varies by area with minimum patch size 20-30 ha in Ohio to 700 ha in Middle Atlantic States to 1,600 ha in the Mississippi Alluvial Valley, but breeding occurs in 10 ha patches in Ontario (summarized by Hamel 2000).
Common Name: Cerulean Warbler  
Scientific Name: Dendroica cerulea  
Species Group: Bird

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

Conversion of Habitat  
Habitat Fragmentation

*Description of habitat problem(s):* Area sensitive in parts of its range, suggesting fragmentation a problem to population. Development or harvest of mature upland forests will decrease available habitat.

*Description of non-habitat problem(s):*
Common Name: Cerulean Warbler
Scientific Name: Dendroica cerulea
Species Group: Bird

Research and Monitoring Needs

<table>
<thead>
<tr>
<th>Type</th>
<th>Need</th>
<th>Priority</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Research</td>
<td>Habitat Requirements</td>
<td>Medium</td>
<td>Species has been relatively well-studied on its breeding range, including recent studies from Ontario. However, better summaries of this information may lead to directed searches for new populations in Vermont. Better information about habitat requirements on the wintering grounds would be useful.</td>
</tr>
<tr>
<td>Research</td>
<td>Basic Life History</td>
<td>Medium</td>
<td>Also relatively well-studied, however more information about non-breeding social system, particularly as to whether or not they are an obligate flock follower.</td>
</tr>
<tr>
<td>Research</td>
<td>Distribution and Abundance</td>
<td>High</td>
<td>1) Directed surveys in Vermont are necessary to better understand their present status in the state. 2) Better information on distribution in Vermont will be critical to conserving the species and predicting future distribution. Intensively monitor (as least of population size) in areas where the species is present.</td>
</tr>
<tr>
<td>Research</td>
<td>Threats and Their Significance</td>
<td>Low</td>
<td>Presumably habitat quality in Vermont will increase as forests mature. However, some information on minimum patch size would help in understanding the effects of development.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Population Change</td>
<td>High</td>
<td>Population trends in Vermont will be difficult to assess without more information on distribution. But all known local populations should be carefully monitored.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Habitat Change</td>
<td>Low</td>
<td>As forest regenerates from abandonment of agricultural lands, habitat will become available through succession. Population response of CERW will be difficult to assess. Forest growth models might be useful in helping to predict future occurrences in the state.</td>
</tr>
</tbody>
</table>

</tr>
</tbody>
</table>

Assessment Narrative:

Declining throughout breeding range, causes not well-documented.

PIF Area 28 priority 1 species. BBS trend for VT, 1966-2003 = -2.71 (p = 0.13); for Multi-state Region 2 (ME, NH & VT) trend = -2.81 (p = 0.02).

Distribution:

Widespread in Vermont.

Natural History Elements:

- Home Range: < 10 ha
- Migrant? Yes
- Within watershed
- Within biophysical region
- Within VT  
- Within Region  
- Within US  
- Outside US

Distribution Summary:

Widespread in Vermont.

Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

A wide range of coniferous and deciduous forests at all elevations, but especially mid-slopes in Green Mountains. Uses both mature and regenerating forest (Conway 1999). Clearcuts and shelterwood cuts received more use than mature forest in northern New Hampshire (King and DeGraff, in press). First appear in clearcuts 5 years after harvest, become common after 15 years and remain abundant until the next cutting cycle (DeGraaf and Yamasaki 2001).
Common Name: Canada Warbler  
Scientific Name: Wilsonia canadensis  
Species Group: Bird

General Habitat Preferences:
- Minimum Elevation (m): 250
- Maximum Elevation (m): 900
- Patch Size Requirements: Unknown
- Prefers large wetland complexes: ☐
- Prefers large expanses of grassland habitat: ☐
- Prefers habitat mosaics: ☐

Miller, N.A. 1999. Landscape and habitat predictors of Canada Warbler (Wilsonia canadensis) and Northern waterthrush (Seiurus noveboracensis) occurrence in Rhode Island swamps. Masters thesis. University of Rhode Island, Kingston, R.I.
Common Name: Rufous-sided Towhee
Scientific Name: Pipilo erythrophthalmus
Species Group: Bird

Conservation Assessment:

Final Assessment: High Priority
Global Rank: G5
Local Rank: S5B
Global Trend: Declining
State Trend: Declining
Extirpated in VT? No
Regionally Rare? No

Assessment Narrative:

PIF moderate priority species for BCR 14. BBS trend in Physiographic Area 28 was -5.1%/year for 1966-1998 (significance = 0.09).

Species declining across region due to conversion of necessary early successional/shrub dominated habitats to either non-forest condition or via maturation of forest cover to an unsuitable forest age structure.

Distribution:

Habitat Description:

Habitat Information is based on the following:

Limited Local Knowledge □ Extensive Local Knowledge □ Regional Literature □ General Literature □

Early-successional/shrub/edge habitats, both mesic and xeric, characterized by dense shrub-small tree cover near ground and well-developed litter layer. Cover may be continuous or discontinuous patches interspersed within more open ground. Overstory trees may or may not be present, however open-canopied woodlands are favored over closed canopy coverage.

Natural History Elements:

Home Range: < 10 ha
Migrant?: Yes
  - Within watershed □
  - Within biophysical region □
  - Within VT □
  - Within Region □
  - Within US ✅
  - Outside US □

<tr>
<td>Regionally Rare?</td>
<td>No</td>
<td></td>
</tr>
</tbody>
</table>

**Assessment Narrative:**

Significant long-term population declines in VT and survey-wide based on BBS data (Sauer et al. 2004). Will likely continue to decline in VT with succession of abandoned farmland to forest (see Carey et al. 2004).

**Distribution:**

**Natural History Elements:**

- **Home Range:** < 10 ha  
- **Migrant?** Yes  
- **Within watershed** ☐  
- **Within biophysical region** ☐  
- **Within VT** ☐  
- **Within Region** ☐  
- **Within US** ☑  
- **Outside US** ☐

**Distribution Summary:**

Data from Ellison (1985).

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge ☑  
- Extensive Local Knowledge ☐  
- Regional Literature ☑  
- General Literature ☑

Difficult to categorize in check boxes. Grasslands with scattered woody vegetation with elevated perches. Habitat declines as woody encroachment progresses. Can be found in orchards and Christmas tree farms (Carey et al. 1994).
Common Name: Field Sparrow
Scientific Name: Spizella pusilla
Species Group: Bird

General Habitat Preferences:
- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements: Unknown
- Prefers large wetland complexes: □
- Prefers large expanses of grassland habitat: □
- Prefers habitat mosaics: ✓
- Prefers actively managed woodland: □
- Requires movement corridors: □
- Prefers large expanses of forest habitat: □

Vegetation Categories Used:
(see Appendix B for habitat, community & landscape organization and conservation summaries)
- Grasslands and Hedgerows

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Conversion of Habitat
- Habitat Succession

Description of habitat problem(s): Primary problems to the species are likely on breeding grounds; continued succession of old fields and conversion of agricultural habitat to urban/suburban development (Carey et al. 1994). Loss of wintering habitat could also be a problem.

Description of non-habitat problem(s):

Research and Monitoring Needs

<table>
<thead>
<tr>
<th>Type</th>
<th>Need</th>
<th>Priority</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Research</td>
<td>Habitat Requirements</td>
<td>High</td>
<td>1) General management practices are likely relatively straightforward. A better understanding of optimal stem densities and mowing rotations would help more specific management strategies. 2) Better information on habitat-specific demographics would enable a more thorough understanding of when and why habitat decreases in quality for FISP.</td>
</tr>
<tr>
<td>Research</td>
<td>Threats and Their Significance</td>
<td>Medium</td>
<td>1) Species could be heavily parasitized by cowbird. Nest predation is the major source of nest mortality (summarized in Carey et al. 1994). 2) Obtain better information about current limiting factors to habitat (development versus succession). Periodic assessment (5 year?) of grassland acreage in Vermont, likely through GIS analysis of Landsat data.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Population Change</td>
<td>High</td>
<td>Improved monitoring would elucidate population distribution and trends. A BBS-type survey route for early successional species could help monitor FISP, BWWA, GWWA, BRTH, PRAW, etc. More intensive demographic data would elucidate BHCO limiting factor.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Habitat Change</td>
<td>High</td>
<td>Succession of old field to forest will continue to limit populations in Vermont and should be monitored. Periodic assessment (5 year?) of grassland acreage in Vermont, likely through GIS analysis of Landsat data.</td>
</tr>
</tbody>
</table>

<th>Extirpated in VT?</th>
<th>Regionally Rare?</th>
</tr>
</thead>
<tbody>
<tr>
<td>S3B</td>
<td>Declining</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Assessment Narrative:**

9.7% decline in VT, statistically significant despite being found on only 11 routes. Also long-term decline survey-wide (Sauer et al. 2004).

The generally small size of farming operations in VT seem as though they should create sufficient habitat to support a larger population in the state. The relative rarity of this species suggests that their habitat requirements may be somewhat more specialized than currently understood.

### Distribution:

#### Natural History Elements:

- **Home Range:** < 10 ha
- **Migrant?** Yes
- **Within watershed** No
- **Within biophysical region** No
- **Within VT** No
- **Within Region** No
- **Within US** Yes
- **Outside US** Yes

#### Distribution Summary:

Data from Ellison (1985).

### Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Breeds in dry, open habitats with short, sparse, and patchy herbaceous vegetation; some bare ground; and low to moderate shrub or tall forb cover. In the East, suitable habitats include reclaimed surface mines, crop and haylands, weedy roadsides, natural meadows, and grasslands (Jones and Cornely 2002).
Common Name: **Vesper Sparrow**  
Scientific Name: *Pooecetes gramineus*  
Species Group: **Bird**

### General Habitat Preferences:

- Minimum Elevation (m): 0  
- Maximum Elevation (m): 3000  
- Patch Size Requirements: > 10 ha  
- Prefers large wetland complexes: ☐  
- Prefers large expanses of grassland habitat: ☐  
- Prefers habitat mosaics: ☑  
- Prefers developed landscapes: ☐  
- Prefers actively managed woodland: ☐  
- Requires movement corridors: ☐  
- Prefers large expanses of forest habitat: ☐

### Vegetation Categories Used:

- Grasslands and Hedgerows  
- Lawns, Gardens, and Row Crops  
- Marshes and Sedge Meadows  
- Open Peatlands  
- Shrub Swamps  
- Wet Shores

### Current Problems:  
(see Appendix C for definitions of problem categories)

#### Habitat Problems:
- Conversion of Habitat  
- Habitat Succession

**Description of habitat problem(s):** Early hay harvest and more intensive management of other row crops substantially reduces nesting success. Conversion of agricultural habitats to urban/suburban development also a problem. Old field succession and farm abandonment also decreasing habitat availability. Area sensitive (Vickery et al. 1994).

**Description of non-habitat problem(s):**

**Assessment Narrative:**

Significant long-term population declines both in VT and survey-wide (Sauer et al. 2004).

Much of VT grasslands are population sinks. As farms are abandoned management strategies to maintain grassland habitat are critical.

**Distribution:**

Data from Ellison (1985).

**Natural History Elements:**

- **Home Range:** < 10 ha
- **Migrant?** Yes
- **Within watershed** ☐
- **Within biophysical region** ☐
- **Within VT** ☐
- **Within Region** ☐
- **Within US** ☐
- **Outside US** ✔

**Distribution Summary:**

Data from Ellison (1985).

**Habitat Description:**

Habitat Information is based on the following:

- **Limited Local Knowledge** ☑
- **Extensive Local Knowledge** ☑
- **Regional Literature** ☑
- **General Literature** ☑

Grasslands, primarily managed. Generally avoids alfalfa, row crops, and grass habitats with standing water during settlement period (late May).
Common Name: Bobolink  
Scientific Name: Dolichonyx oryzivorus  
Species Group: Bird

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Conversion of Habitat
- Habitat Alteration
- Habitat Succession

Description of habitat problem(s): Greatest problems are the widespread early hay harvest (early June), continued decrease of agriculture and abandonment of agricultural land, and the conversion of agricultural habitat to urban/suburban development (Martin and Gavin 1995, Troy et al. in press).

Description of non-habitat problem(s):

#### Bibliography:

Common Name: Rusty Blackbird  
Scientific Name: Euphagus carolinus  
Species Group: Bird

Conservation Assessment:

Final Assessment: Medium Priority  
Global Rank: G5  
State Rank: S3B  
Extirpated in VT? No  
Regionally Rare? Yes

Assessment Narrative:

Ellison (1990) suggested no appreciable decline in Caledonia and Essex counties between 1982 - 1991. The recent recovery of beaver populations is believed to have increased available nesting habitat and benefited rusty blackbirds in the Adirondacks (Peterson 1988). "Wet forested habitat preferred by Rusty Blackbirds is relatively inaccessible and somewhat inhospitable, so breeding populations may be in no imminent danger, but more careful monitoring … is needed to confirm this." (Avery 1995).

Distribution:

Natural History Elements:

Home Range: Unknown  
Migrant? Yes  
Within watershed  
Within biophysical region  
Within VT  
Within Region  
Within US  
Outside US

Distribution Summary:

"Rusty Blackbirds are local and uncommon summer residents of the Northeast Highlands, the North Central region, and the Green Mountains." (Nichols 1985)

Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge  
- Extensive Local Knowledge  
- Regional Literature  
- General Literature

Wooded swamps, tree-bordered marshes, beaver ponds, boreal bogs and stream borders with alder and willow thickets (DeGraff and Rudis 1986). "Disturbance can be favorable to this species; e.g., nests found in modest openings regenerating from clearcuts (Ellison 1990)" (Avery 1995).
Common Name: Rusty Blackbird  
Scientific Name: Euphagus carolinus  
Species Group: Bird

General Habitat Preferences:
- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements: Unknown
- Prefers large wetland complexes: □
- Prefers large expanses of grassland habitat: □
- Prefers habitat mosaics: □
- Prefers developed landscapes: □
- Prefers actively managed woodland: □
- Requires movement corridors: □
- Prefers large expanses of forest habitat: □

Vegetation Categories Used:
(see Appendix B for habitat, community & landscape organization and conservation summaries)
- Early Succession Boreal Conifers
- Early Succession Northern Hardwoods
- Early Succession Spruce-Fir
- Hardwood Swamps
- Shrub Swamps
- Softwood Swamps

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
Conversion of Habitat

Description of habitat problem(s): Permanent residence and/or vacation home development on lakeshores/pondshores may reduce available habitat.

Non-Habitat Problems:
Harvest or Collection

Description of non-habitat problem(s): "Substantial mortality to local populations may occur when Rusty Blackbirds are in mixed-species winter roosts subjected to blackbird control in the s. U.S.(Stickley et al. 1986)" (Avery 1995).

</table>
The blueback herring population in the Connecticut River has declined significantly over the past two decades to the extent that now it is rarely observed in the Vermont-New Hampshire section of the river. Population abundance as represented by annual fish passage counts at the Holyoke Dam fish lift in Massachusetts provides the best relative estimate of the species status in the Connecticut River basin. In the 12-year period, 1981-1992, annual herring passage averaged 433,000. In contrast, during the 1990s passage counts at Holyoke declined dramatically with an average of only 44,000 passed annually. Since then herring numbers have continued to drop with 1,939 fish counted in 2002 and only a couple hundred in 2004. Population estimates made at the Vernon Dam fish ladder, while always significantly lower than numbers counted further downstream have followed a similar declining trend with no blueback herring being recorded in some years. Three noteworthy blueback herring restoration/management plans exist for the conservation of this species: "1999 Review of the ASFMC Fishery Management Plan for Shad and River Herring (Alosa spp.)" developed by the Atlantic States Fisheries Management Council, the "Management Plan for Blueback Herring in the Connecticut River Basin (2003)" prepared by the Connecticut River Atlantic Salmon Commission, and the "Plan for the restoration of migratory fishes to the Ashuelot River basin, New Hampshire." These plans specify management goals and objectives for blueback herring restoration and conservation including target population levels, overfishing, habitat improvement, fish passage, and outmigrant survival. Blueback herring are not indigenous to Lake Champlain but got access to the lake via the likely route of the Hudson Barge Canal.
Blueback herring is an anadromous species spending portions of its life in both marine and freshwater environments. In freshwater, it migrates up rivers to spawn. Generally the upstream migration of blueback herring does not extend as far as for other clupeid species (e.g., alewife); spawning may occur in both brackish and fresh waters (Scott and Crossman 1973). Spawning occurs in a diversity of habitats, including large rivers, small streams, ponds and large lakes over a range of substrates, such as gravel, sand, detritus, and submersed vegetation and other structures. Swift flowing waters are used as spawning sites. Blueback herring spawn in rivers releasing their eggs into the water column whereupon the eggs settle and adhere to the substrate, including stones, gravel and sticks (Scott and Crossman 1973). Larval and juvenile blueback herring reside in the river during their first summer before outmigrating the following fall. Spawning success and survival of adults and juveniles are dependent on successful passage past manmade obstacles, such as dams and hydroelectric generation plants.

### Known Watersheds

CT-Ashuelot River

CT-Bellows Falls Dam to Vernon Dam

### Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Blueback herring is an anadromous species spending portions of its life in both marine and freshwater environments. In freshwater, it migrates up rivers to spawn. Generally the upstream migration of blueback herring does not extend as far as for other clupeid species (e.g., alewife); spawning may occur in both brackish and fresh waters (Scott and Crossman 1973). Spawning occurs in a diversity of habitats, including large rivers, small streams, ponds and large lakes over a range of substrates, such as gravel, sand, detritus, and submersed vegetation and other structures. Swift flowing waters are used as spawning sites. Blueback herring spawn in rivers releasing their eggs into the water column whereupon the eggs settle and adhere to the substrate, including stones, gravel and sticks (Scott and Crossman 1973). Larval and juvenile blueback herring reside in the river during their first summer before outmigrating the following fall. Spawning success and survival of adults and juveniles are dependent on successful passage past manmade obstacles, such as dams and hydroelectric generation plants.

### General Habitat Preferences:

- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements:
  - Prefers large wetland complexes: □
  - Prefers large expanses of grassland habitat: □
  - Prefers habitat mosaics: □
  - Prefers developed landscapes: □
  - Prefers actively managed woodland: □
  - Requires movement corridors: □
  - Prefers large expanses of forest habitat: □

### Vegetation Categories Used:

Aquatic: Lower CT River

(see Appendix B for habitat, community & landscape organization and conservation summaries)

### Current Problems: (see Appendix C for definitions of problem categories)

#### Habitat Problems:

Habitat Fragmentation

**Description of habitat problem(s):** Spawning success and survival of adults and juveniles are limited by the existence and development of dams and hydroelectric generation plants which may impede access to spawning and nursery habitats, as well as cause mortality to outmigrating fish. River flow regimes as manipulated by hydroelectric power generation activities can affect blueback herring habitat.

#### Non-Habitat Problems:

Predation or Herbivory

**Description of non-habitat problem(s):** Migrating adult and juvenile blueback herring are susceptible to predation, especially fish predators. Improvements in stock strength of striped bass and bluefish are believed to have increased predatory pressure on migrating clupeid populations, including blueback herring and American shad. Being an anadromous species, blueback herring are subjected to a wide variety of problems associated with extensive migrations and residency in both marine and freshwater environments. Outmigrating adult and juvenile herring may be exposed to turbine mortality at power dams resulting in high mortality.

**Assessment Narrative:**

The only landlocked salmon population in Vermont with some level of documented natural reproduction occurs in Lake Memphremagog and the Clyde River. Historically, landlocked salmon inhabited Lake Champlain. The Lake Champlain Fish and Wildlife Management Cooperative is currently engaged in a program to restore landlocked salmon to the Lake Champlain basin.

  - **Outside US:** ☐

### Natural History Elements:

- **Distribution Summary:**
  Landlocked populations of Atlantic salmon occur principally in Newfoundland, Labrador and Quebec (Scott and Crossman 1973). Natural populations were also located in Maine and presumably in Vermont, i.e. lakes Champlain and Memphremagog. Scarola (1973) reports all landlocked salmon populations in New Hampshire are introduced. Landlocked populations have been stocked extensively to supplement natural populations, as well as to establish new fisheries. Even though salmon still occur in Lake Champlain, this is principally the result of a stocking program designed to restore a naturally reproducing population to the watershed, albeit there is little evidence of significant natural reproduction occurring there at this time. The Lake Memphremagog population does reproduce naturally with spawning occurring in the Clyde River.

### Known Watersheds

- Saint-Francois River
Species: Atlantic Salmon (landlocked)  
Scientific Name: Salmo salar (landlocked)  
Species Group: Fish

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

The landlocked salmon is a fish of oligotrophic waters, that is deep, well oxygenated, relatively infertile lakes. As the spawning season sets in fish leave the depths of the lake to suitable spawning habitat located in shallow lake shore areas or to ascend tributary streams or use lake outlets (Scarola 1973). Habitat studies conducted in Lake Winnipesaukee, New Hampshire found the salmon have a preference for depths below the thermocline during the summer period (12-21 m) (Scarola 1973). Water temperatures at this time of year are in the mid 10s (C). Salmon can survive water temperatures into the 21s for brief periods of time but such temperatures are usually avoided if cooler water is available. Longer exposure to these temperatures can cause the fish physiological stress. Temperatures into the 27s can be lethal. Spawning habitat preferences are similar to those for anadromous Atlantic salmon.

**General Habitat Preferences:**

- Minimum Elevation (m): 208
- Maximum Elevation (m): -1
- Patch Size Requirements:
  - Prefers large wetland complexes: 
  - Prefers large expanses of grassland habitat: 
  - Prefers habitat mosaics: 
  - Prefers developed landscapes: 
  - Prefers actively managed woodland: 
  - Requires movement corridors: 
  - Prefers large expanses of forest habitat: 

**Vegetation Categories Used:**

- Aquatic: Fluvial
- Aquatic: Lake Champlain
- Aquatic: Large Lake Champlain Tribs Below Falls

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Climate Change
- Habitat Alteration
- Habitat Fragmentation
- Invasion by Exotic Species
- Sedimentation

**Description of habitat problem(s):** Salmon require cool streams for spawning and juvenile rearing. Many of the historical salmon streams in Vermont have barriers that impede their access to these habitats (e.g., Missisquoi, Lamoille, Winooski, Clyde rivers and Otter Creek). Dams and other impassable barriers, such as culverts, also fragment habitats that are needed to access spawning and rearing habitats but also for seasonal movements (e.g., summer feeding, temperature refugia, overwintering habitats). Water quality degradation, such as in mean annual temperatures, have occurred due to losses in mature riparian canopies, impacts from land use practices, urban stormwater runoff, and water retention in impoundments. Stream habitats have been degraded and habitat complexity decreased from channelization and removal and reduced recruitment of large woody debris to rivers. Habitat degradation from a variety of stressors has
Atlantic Salmon (landlocked)

Salmo salar (landlocked)

Fish

reduced the quality of spawning and juvenile rearing habitats in Vermont streams. The appearance of alewife in Lake Champlain is of great concern due to their potential impact through competition with other pelagic planktivores, such as landlocked Atlantic salmon.

Non-Habitat Problems:

- Competition
- Genetics
- Parasites

Description of non-habitat problem(s): The native stocks of landlocked salmon in Lake Champlain were extirpated by the mid 1800s. It is questionable whether past and current restoration efforts are using genetically appropriate strains for restoration given the habitat conditions present in the lake. Competition and displacement by introduced salmonids, such as rainbow trout, may impact juvenile rearing stages of salmon. Sea lamprey parasitism has been found to be a significant source of mortality affecting salmon restoration.

**Conservation Assessment:**

| Final Assessment: High Priority | Global Rank: G4 | Global Trend: Unknown |  
| State Rank: S1 | State Trend: Unknown |  
| Extirpated in VT? No | Regionally Rare? Yes |  

**Assessment Narrative:**

In Vermont, the northern brook lamprey is a state listed endangered species; and, in Quebec, it is a species of special concern. Only one population is known to occur in the state encompassing two streams in the Lake Champlain biophysical region (Indian Brook and Malletts Creek). This population is at the eastern edge of its continental range. Plans for controlling sea lamprey in Lake Champlain do not appear to pose a limiting factor to northern brook lamprey at this time. The more serious limiting factor to the species is habitat loss and degradation. The Indian Brook-Malletts Creek watershed is located within a rapid development area, where point and non-point discharges to these waters are sources of sediments, pollutants and contaminants. Due to the small size of the population the potential for inbreeding depression is also a concern. Northern brook lamprey is a nonparasitic species.

**Distribution:**

**Natural History Elements:**

- **Within watershed** ✔  
- **Within biophysical region** ☐  
- **Within VT** ☐  
- **Within Region** ☐  
- **Within US** ☐  
- **Outside US** ☐

**Distribution Summary:**

Northern brook lamprey occur in the Mississippi and Great Lakes drainages from western New York, Quebec, Ontario, Michigan and eastern Wisconsin; from the north shore of Lake Superior to northern Indiana and Ohio (Scott and Crossman 1973). Only one northern brook lamprey population is known in Vermont. This population is limited to one watershed consisting of Indian Brook and Malletts Creek, both tributaries of Malletts Bay on Lake Champlain.

**Known Watersheds**

- Lake Champlain Direct

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Clear streams and small to moderate sized rivers (Scott and Crossman 1973; Smith 1985; Langdon et al, in press; Morman 1979). The non-parasitic northern brook lamprey spends its entire life in streams. No known populations reside on Lake Champlain's deltas, unlike sea lamprey and American brook lamprey. It has a 4 to 6 year life span and spends most of it buried in the substrate, where it grows to about 150mm, metamorphoses, and becomes sexually mature. Adults generally migrate upstream to spawn. Larval habitat includes lotic depositional and estuarine areas of streams with organic matter for feeding and fairly stable substrate in order to maintain burrow. Stream riffle areas with sand and pea gravel up to approximately 15 mm diameter are used for spawning (W. Bouffard, USFWS, personal communication). Spawning water depth is typically <450 mm deep (Scott and Crossman 1998).

</tr>
</tbody>
</table>

### Vegetation Categories Used:

- Aquatic: Fluvial
- Aquatic: Large Lake Champlain Tribs Below Falls

### Current Problems:

(see Appendix C for definitions of problem categories)

**Habitat Problems:**

Habitat Alteration  
Habitat Fragmentation  
Sedimentation

**Description of habitat problem(s):** Culverts at road crossings may fragment habitat by creating barriers to the upstream migration of spawning adult northern brook lamprey. Sedimentation of stream bottoms reduces the quality of spawning habitat. The lower reaches of Malletts Creek and Indian Brook, which converge to form a large wetland complex, may reach the lethal temperature limit of 30.5 °C thereby limiting population distribution in those streams.

**Non-Habitat Problems:**

Competition  
Genetics  
Pollution

**Description of non-habitat problem(s):** Due to the small population size, distance from other regional
northern brook lamprey populations, and absence of gene flow between populations, there is a potential for inbreeding depression to occur naturally within Vermont's population. No diagnostic characteristics exist for differentiating between northern brook and silver lamprey accomocetes. These two species were not readily distinguishable using mitochondrial sequence and mitochondrial restriction fragment length polymorphism analyses, raising the question whether they are different species or different ecomorphotypes (Mandrak et al. 2004). This presents difficulties in understanding current distributions and population trends for northern brook lamprey in the Lake Champlain basin. Competition for larval habitat with sea lamprey and silver lamprey could reduce survival and/or fitness of northern brook lamprey larvae. Small population sizes and extremely limited geographic distribution increase the vulnerability of the population to a potential pollution event. The Lake Champlain Fish and Wildlife Management Cooperative is currently involved in a sea lamprey control program that includes the use of lampricides to kill stream-resident sea lamprey larvae. These lampricides are toxic to all species of lamprey. Currently, sea lamprey are being controlled in streams with northern brook lamprey through the use of traps, eliminating the need for lampricides. The repeated use of lampricides has been shown to adversely affect populations of northern brook lamprey in Lake Superior tributaries (Schuldt and Goold 1980).

### Habitat Restoration

- **Habitat Restoration**: High
  - Protect and restore in-stream and riparian habitats via water quality improvements, flows, temperature, sediment reduction, streamside buffers, and maintenance of in-stream habitat structure (e.g., large woody debris).
  - Develop a northern brook lamprey stream habitat protection and management plan.

### Bibliography:

- Vladykov, V.D. 1951. Fecundity of Quebec lampreys. Canadian Fish Culturist (10):1-14
The silver lamprey is a widely distributed and relatively common species in Lake Champlain and occurs in 11 Vermont tributaries. The Vermont population is on the eastern edge of its continental range. Habitat fragmentation resulting from the construction of passage barriers (e.g., road culverts) and habitat degradation, such as sedimentation, are limiting factors to the species. However, the treatment of its spawning and nursery habitats with lampricides for the control of sea lamprey in Lake Champlain may be a more formidable challenge facing the species' security in Vermont.

Distribution:

Silver lamprey are restricted to eastern North America, from the St. Lawrence River as far down as Montmagny, Quebec, west through the Great Lakes, through the upper Mississippi valley from Wisconsin, to eastern Manitoba; from Manitoba tributaries of Hudson Bay in the north to the Ohio River basin as far south as Kentucky (Scott and Crossman 1973). In Vermont, this species is at the eastern edge of its North American range. Vermont populations are limited to Lake Champlain and the lower reaches of several tributaries up to the fall line.

Known Watersheds

**Assessment Narrative:**

In Vermont, the American brook lamprey is a state listed threatened species. Known populations in the state number four distributed among seven streams, all located within the Lake Champlain biophysical region (Missisquoi River, including Kelly, Hungerford and Youngman brooks; Trout Brook; and Winooski River, including Sunderland Brook). Some populations are limited by the use of lampricides to control sea lamprey in Lake Champlain and tributaries used for spawning. Other limiting factors to the species in Vermont are habitat fragmentation caused by the construction of fish passage barriers, such as road culverts, and the degradation of spawning habitat by sedimentation originating primarily from non-point land-based sources. American brook lamprey is a nonparasitic species.

**Distribution:**

American brook lamprey is restricted to east-central North America: on the eastern seaboard from southeastern New Hampshire south to Maryland; and in the St. Lawrence River and tributaries from Montmagny southwest through the Great Lakes, west to southeastern Minnesota, south into the Mississippi River drainage to Tennessee and Missouri (Scarola 1973; Scott and Crossman 1973). In Vermont, it is known to occur in the Missisquoi River and tributaries, Hungerford and Kelly brooks; Winooski River, and its tributary, Sunderland Brook; Youngman Brook; and Trout Brook.

**Known Watersheds**

Lake Champlain Direct
Clear, cool streams and small rivers characterized by a large proportion of groundwater inflow (Scott and Crossman 1973; Smith 1985; Langdon et al., in press; Morman 1979). The non-parasitic American brook lamprey spends its entire life in streams and infrequently migrates to lakes, except to reside on some Lake Champlain river deltas particularly in New York, i.e. Ausable and Salmon rivers (Langdon et al. in press). It has a 4 to 6 year life span and spends most of it buried in the substrate, where it grows to about 200mm, metamorphoses, and becomes sexually mature. Adults generally migrate upstream to spawn. American brook lamprey spawn the earliest and initiate spawning in the coolest water (~7°C)(Hardisty and Potter 1971) compared to other species of lamprey in the Lake Champlain Basin. Larval habitat consists of lotic depositional, estuarine, and lentic areas of streams, with organic matter for feeding and fairly stable substrate in order to maintain burrow. Spawning occurs in riffle areas with sand and pea gravel up to approximately 20 mm diameter (Manion and Hanson 1980; W. Bouffard, USFWS, personal communication). Adults require certain physical factors for successful spawning such as suitable substrate (pea gravel), water velocities (0.3-0.5 m/s), and temperatures (mean 14°C, range 6.7-20.6°C) (Manion and Hanson 1980; Hardisty and Potter 1971; Morman 1979).

**Current Problems:**

(see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Habitat Alteration
- Habitat Fragmentation
- Sedimentation

**Description of habitat problem(s):** Culverts at road crossings and dams may fragment habitat by creating barriers to upstream spawning migration of adult brook lamprey. Sedimentation of stream bottoms reduces the quality of spawning habitat.

**Non-Habitat Problems:**

- Competition

**Description of non-habitat problem(s):** Competition for larval habitat with sea lamprey and silver lamprey
Common Name: American Brook Lamprey  
Scientific Name: Lampetra appendix  
Species Group: Fish  

may reduce survival and/or fitness of American brook lamprey larvae (Scott and Crossman 1998). The Lake Champlain Fish and Wildlife Management Cooperative is currently involved in a sea lamprey control program that includes the use of lampricides to kill stream-resident larvae. These lampricides are toxic to all species of lamprey. In most streams where American brook lamprey and sea lamprey co-occur, traps are used to remove adult sea lamprey before they spawn, eliminating the need to use lampricides. The repeated use of lampricides has been shown to adversely affect populations of American brook lamprey in Lake Superior tributaries (Schuldt and Goold 1980).

Conservation Assessment:

Final Assessment: Medium Priority
Global Rank: G5
State Rank: S4S5
Global Trend: Stable
State Trend: Stable
Exirpated in VT? No
Regionally Rare? No

Assessment Narrative:

Sea lamprey of the Connecticut River basin were extirpated from Vermont about 200 years ago at about the same time anadromous Atlantic salmon and American shad were eliminated from the basin as a result of the construction of fish passage barriers and the degradation of spawning and nursery habitats. The retrofitting of dams on the river, including the Vernon dam in 1981, restored lamprey access to spawning waters. Currently, sea lamprey spawn in the Connecticut River main stem at least as far upstream as Wilder dam, as well as many of the tributaries along the way, such as the West, Williams, Black and White rivers. The most significant limiting factor to this species in the Connecticut River basin is fish passage obstruction. Continued operation and maintenance of existing fishways and the removal or mitigation of other barriers is necessary to assure this species security in Vermont. Another limiting factor to the species is sedimentation of its spawning habitats. At the present time the sea lamprey population in the Connecticut River basin appears to be path to recovery. Unlike the landlocked sea lamprey inhabiting Lake Champlain, the anadromous Connecticut River population does not feed in freshwater and, therefore, is not a threat to other Vermont fishes.

Distribution:

Known Watersheds
CT-Ashuelot River
CT-Bellows Falls Dam to Vernon Dam
CT-White River to Bellows Falls

Possible Watersheds
CT-Waits River to White River

Natural History Elements:

Within Region
Within US
Outside US

Distribution Summary:

Sea lamprey are common on both sides of the Atlantic Ocean; in the west, from southwestern Greenland and the Grand Banks, the Gulf of St. Lawrence, and as far up the St. Lawrence River and its tributaries as Sorel, Quebec, and south to northeastern Florida (Scott and Crossman 1973). Landlocked populations also exist, such as the one in Lake Champlain. Adult sea lamprey frequent the Connecticut River and many of its larger tributaries up to the first impassable barriers during the spawning season. Larval lamprey inhabit these waters wherever suitable habitat exist.
Common Name: Sea Lamprey (CT river only)
Scientific Name: Petromyzon marinus (CT river only)
Species Group: Fish

White River

**Habitat Description:**

Habitat Information is based on the following:
- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Anadromous populations of sea lamprey, as occurs in the Connecticut River basin, have a life cycle that depends on both marine and freshwater habitats. Adults migrate from the sea and ascend rivers and streams to spawn. Spawning occurs over substrate composed of a mixture of sand, gravel and rubble at water depth of 381-610 mm. Spawning activity starts when stream water temperature warms to 11.1-11.7 C and peaks at 14.4-15.6 C (Scott and Crossman 1973). Larvae take up residence by burrowing into rich organic stream bottoms and feed at the streambed surface by filtering out food organisms.

**General Habitat Preferences:**

- Minimum Elevation (m): 0
- Maximum Elevation (m): 0

**Patch Size Requirements:**
- Prefers large wetland complexes:
- Prefers large expanses of grassland habitat:
- Prefers habitat mosaics:
- Prefers developed landscapes:
- Prefers actively managed woodland:
- Requires movement corridors:
- Prefers large expanses of forest habitat:

**Vegetation Categories Used:**

- Aquatic: Fluvial
- Aquatic: Lake Champlain
- Aquatic: Lower CT River

(see Appendix B for habitat, community & landscape organization and conservation summaries)

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Habitat Fragmentation
- Sedimentation

**Description of habitat problem(s):** Excessive siltation degrades the quality of spawning habitat. Migration barriers (e.g., dams) fragment habitat and can prevent adults from gaining access to spawning areas.

**Description of non-habitat problem(s):**

<tr>
<td>Extirpated in VT? No</td>
<td>Regionally Rare? No</td>
<td></td>
</tr>
</tbody>
</table>

Assessment Narrative:

In Vermont, the mottled sculpin has a very restricted distribution with only seven populations identified to date, all located in the northern Champlain Valley biophysical region. Even though the habitat of this species is generally described as cold or cool water, populations in Vermont are frequently found in warm water downstream of the principal fall line. This suggests Vermont populations may be at risk to habitat degradation, including warming temperature regimes, as well as increased sedimentation, pollutants and contaminants.

Distribution:

![Biophysical Regions in Vermont Diagram]

Natural History Elements:

- Home Range: Unknown
- Migrant? No
- Within watershed:  
- Within biophysical region:  
- Within VT:  
- Within Region:  
- Within US:  
- Outside US:  

Distribution Summary:

The mottled sculpin has a wide but discontinuous distribution in North America with the more eastern range encompassing northern Quebec and Labrador, and the drainages of the Great Lakes, Hudson and James bays. Western populations are largely limited to the Columbia River drainage (Scott and Crossman 1973). In Vermont, seven populations of mottled sculpin have been identified, all in tributaries to northern Lake Champlain (Allen Brook, Colchester; Bartlett Brook, South Burlington; Englesbee Brook, Burlington; Lamoille River, Milton; Mill River, Georgia; Stonebridge Brook, Milton; Trout Brook, Milton. It is also suspected to inhabit shoreline areas of Lake Champlain.

Known Watersheds

Lake Champlain Direct

Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge:  
- Extensive Local Knowledge:  
- Regional Literature:  
- General Literature:  

Mottled sculpin occur in cool streams, small rivers and in lakes. It prefers a bottom of gravel or rubble, rarely being found over sand. In streams it is a riffle dweller. In lakes it inhabits rocky shorelines. Although most reports label mottled sculpin as a cold or cool water species, Vermont specimens have been recorded in
warmer streams below the fall line (Langdon et al. In press). Mottled sculpin are found in areas with substrates composed of clean gravel and rubble/cobble. They are intolerant of habitat degradation (siltation and turbidity) and populations have been reduced in some parts of its range. Spawning takes place in cavities beneath rocks, ledges, or logs generally in May when water temperatures reaches 10 C (Smith 1985; Trautman 1981).

**General Habitat Preferences:**

- Minimum Elevation (m): 29
- Maximum Elevation (m): 45

**Patch Size Requirements:**

- Prefers large wetland complexes: □
- Prefers large expanses of grassland habitat: □
- Prefers habitat mosaics: □
- Prefers developed landscapes: □
- Prefers actively managed woodland: □
- Requires movement corridors: □
- Prefers large expanses of forest habitat: □

**Vegetation Categories Used:**

Common Name: Mottled Sculpin
Scientific Name: Cottus bairdi
Species Group: Fish

Bibliography:
In Vermont, the lake sturgeon is a state listed endangered species. The only population in the state occurs in Lake Champlain and in the low elevation reaches of the lake's largest tributaries (Missisquoi, Lamoille and Winooski rivers and Otter Creek). This population is at the eastern edge of its continental range. Lake sturgeon is limited by habitat loss and degradation as a result of construction of migration barriers eliminating access to historic spawning waters, sedimentation altering spawning habitat and egg survivial, and life history characteristics, such as age of maturation and spawning frequency, and low population size which presents the potential for inbreeding depression. Lake sturgeon were harvested commercially until 1967. Relatively little is known about the species in Vermont, such as abundance and age structure of the adult population, spawning, survival from egg to adult life stages, and genetic characteristics of the population.

Distribution:

Lake sturgeon has a wide distribution occurring from the St. Lawrence River to Hudson Bay, west to the Saskatchewan River in Alberta, south through Lake Champlain, the Mississippi River to the Tennessee River in Alabama and in northern Mississippi; from lakes Winnipeg and Manitoba south through eastern North and South Dakota, northeaster Nebraska and Kansas to eastern Missouri and Arkansas (Scott and Crossman 1973). In Vermont, it inhabits only Lake Champlain and spawns in its larger tributaries (Missisquoi, Lamoille, Winooski rivers and Otter Creek). The Vermont population is on the eastern edge of the species North American range.

Known Watersheds
Lake Champlain Direct
Lamoille River
Mississquoi River
Lake Sturgeon

**Scientific Name:** *Acipenser fulvescens*

**Species Group:** Fish

Lake Sturgeon is a demersal species inhabiting lakes and large rivers, usually at 5-9 m depth, over mud, sand, and gravel (Page and Burr 1991). Sturgeon inhabiting Hudson bay and the Gulf of St Lawrence have occasionally been observed entering brackish water (Page and Burr 1991). Typical spawning sites are rocky and boulder filled areas at the outside bend of rivers.

### General Habitat Preferences:
- **Minimum Elevation (m):** 29
- **Maximum Elevation (m):** 45
- **Patch Size Requirements:**
  - Prefers large wetland complexes:  
  - Prefers large expanses of grassland habitat:  
  - Prefers habitat mosaics:  
  - Prefers developed landscapes:  
  - Prefers actively managed woodland:  
  - Requires movement corridors:  
  - Prefers large expanses of forest habitat:  

### Habitat Description:
Habitat Information is based on the following:
- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Lake Sturgeon eggs require clean river bottoms for survival and the species has declined in areas where siltation has been high. Dams fragment habitat and create barriers to upstream migrating fish during the spawning season.

### Current Problems:
(see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Habitat Alteration
- Habitat Fragmentation
- Sedimentation

**Description of habitat problem(s):** Lake sturgeon eggs require clean river bottoms for survival and the species has declined in areas where siltation has been high. Dams fragment habitat and create barriers to upstream migrating fish during the spawning season.

**Non-Habitat Problems:**
- Genetics
- Harvest or Collection
- Pollution
- Reproductive Traits

**Description of non-habitat problem(s):** Lake sturgeon are long-lived. Maturity is attained at 14-20 years, and thereafter reproduction occurs approximately every four years. These life history characteristics make lake sturgeon extremely vulnerable to harvest and other disturbances. Lake sturgeon populations exhibit

Common Name: Lake Sturgeon
Scientific Name: *Acienser fulvescens*
Species Group: Fish

Long recovery times because of delayed maturation and the number of years between spawning events. Low population size could lead to inbreeding depression. Over-harvest by sport and commercial fishermen prior to closure of the Vermont fishery in 1967 may have contributed to the decline of the species in Lake Champlain.

American eel use to be an abundant species in both Connecticut and Lake Champlain drainages. As recently as the early 1980s, it was harvested commercially in Lake Champlain. For at least 150 years the Richelieu River, which flows out of Lake Champlain, supported a significant commercial eel fishery. Canadian fishery scientist estimated the average annual eel harvest between 1920 and 1980 was 35 metric tons; however, since 1981 landings have decreased from 72.9 tons to only 4.7 tons (Dumont et al. 2004). Today in Vermont, it is rarely encountered. The construction of large dams on rivers once ascended by eels have blocked juvenile fish access to critical rearing habitats. Dams used for hydropower generation have also been implicated in causing high levels of mortality as eels are subjected to turbine losses during their outmigration to sea. High commercial harvest of juvenile eels in coastal waters has further contributed to depressed U. S. stocks. Global climate change has also been identified as a potential limiting factor. The current status of American eel on a national level has given support to the species being recommended for federal endangered species designation. In 2000, the Atlantic States Marine Fisheries Commission adopted an "Interstate Fishery Management Plan for American eel."

The American eel occurs from Greenland throughout much of eastern Canada, south through most of eastern United States to the Gulf coast, along the eastern seaboard of Mexico to the Yucatan Peninsula, the West Indies and Bermuda to the Gulf of Mexico, Panama and the West Indies and Bermuda (Scott and Crossman 1973). Spawning grounds are in the Sargasso Sea. In Vermont, eel historically were found through much of Vermont (Lake Champlain and Connecticut River drainages).

**Known Watersheds**

- CT-Ashuelot River
- CT-Bellows Falls Dam to Vernon Dam
- CT-Waits River to White River

**Distribution Summary:**

The American eel occurs from Greenland throughout much of eastern Canada, south through most of eastern United States to the Gulf coast, along the eastern seaboard of Mexico to the Yucatan Peninsula, the West Indies and Bermuda to the Gulf of Mexico, Panama and the West Indies and Bermuda (Scott and Crossman 1973). Spawning grounds are in the Sargasso Sea. In Vermont, eel historically were found through much of Vermont (Lake Champlain and Connecticut River drainages).
American Eel is a catadromous species and is reported to only spawn in the Sargasso Sea of the Atlantic Ocean. Larvae are carried by ocean currents to coastal areas where they transform into glass eels, then elvers and begin a long upstream migration to inland waters where they can live in excess of 20 years (as immature yellow eels) before returning to the sea to spawn (silver eels). The only life stages occurring in Vermont is the immature yellow phase and at the beginning of their downstream migrating the silver phase. Yellow-phase American eels have occurred in both the Connecticut River and Lake Champlain drainages of Vermont, where they can live in a wide variety of habitats including ponds, lakes, rivers and streams. They often occupy areas where they can find cover (rocks, snags, weeds) during daylight hours.

**General Habitat Preferences:**

Aquatic: Lacustrine
Aquatic: Lake Champlain
Aquatic: Large Lake Champlain Tribs Below Falls
Aquatic: Lower CT River
Aquatic: Man-Made Water Bodies

**Current Problems:**

**Habitat Problems:**

Climate Change
Habitat Fragmentation

*Description of habitat problem(s):* American eels migrate into Vermont from the Atlantic Ocean. Therefore, obstructions, such as dams, in the migration route can fragment habitat and limit access. Recent studies by Knights (2003) and Wirth and Bernatchez (2003) suggest that climate change may be affecting ocean temperatures and currents such that food and dispersal of eel larvae have been negatively impacted, thereby reducing survival and recruitment.

**Non-Habitat Problems:**

Harvest or Collection
Common Name: American Eel  
Scientific Name: Anguilla rostrata  
Species Group: Fish

Pollution  
**Description of non-habitat problem(s):** For decades, eels from Lake Champlain have been harvested in Canada as they migrate out along the Richelieu and St. Lawrence rivers. This has also occurred elsewhere throughout the range of the species in North America. In addition, eels were harvested for commercial sale in Vermont waters of Lake Champlain by electrofishing for a few years in the 1980s. The commercial harvest of eels in Lake Champlain was made illegal in 2002. In-migrating glass eels and elvers have also been harvested in coastal areas and tributaries of North America for many years and shipped to Asia to supply aquacultural operations. Commercial exploitation has contributed to over-harvested eel stocks. Given the long length of time American eels can reside in freshwater and being piscivores pollution may contribute to bio-accumulation of contaminants in their tissues. Being a catadromous species, American eel are subjected to a wide variety of problems associated with extensive migrations and residency in both marine and freshwater environments. During outmigration from freshwater rearing waters to saltwater silver eels can exposed to high mortality having to pass through turbines at hydroelectric power dams.

### Bibliography:

Common Name: American Shad
Scientific Name: Alosa sapidissima
Species Group: Fish

Conservation Assessment:

Final Assessment: Medium Priority
Global Rank: G5
State Rank: S4
Global Trend: Declining
State Trend: Declining
Exirpated in VT? No
Regionally Rare? No

Assessment Narrative:

American shad in the Connecticut River basin appears to be reasonably secure as long as access to spawning and nursery habitats is not obstructed by construction of new dams and fish passage facilities (e.g., fish ladders) at existing dams continue to be operated and maintained during critical times of the year. Other limiting factors to the species, such as harvest and predation, are factors that are exerting pressure on the population largely outside the upper Connecticut River basin. Size of annual adult spawning runs into the shared Vermont-New Hampshire section of the Connecticut River have declined since peak years of the early 1990s. This appears to be largely attributed to the inefficiency of fishways at dams on the river at Turners Falls, Massachusetts. Mortality of outmigrating adult and juvenile shad exposed to turbine passage at hydroelectric power dams continues to be a concern of fishery agencies.

Distribution:

American shad inhabit waters along the Atlantic Coast from Newfoundland south to Florida; it has also been introduced to the Pacific Coast of North America (Scott and Crossman 1973). In Vermont, it is restricted to the Connecticut River from the Massachusetts line upstream to at least Bellows Falls dam. Low numbers in some years are passed above Bellows Falls via the fish ladder there. Shad have also been observed in the lower West River.

Natural History Elements:

Home Range: Yes

Known Watersheds

CT-Ashuelot River
CT-Bellows Falls Dam to Vernon Dam
CT-White River to Bellows Falls
Common Name: American Shad  
Scientific Name: Alosa sapidissima  
Species Group: Fish

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

As an anadromous fish, the American shad divides its life between marine and freshwater environments. Adults ascend rivers and streams to spawn. Once the eggs hatch, larval and juvenile shad inhabit riverine habitats, including setbacks, through their first summer of life before outmigrating to the ocean in the fall. Maturity is attained at sea. Stier and Crance (1985) review the habitat requirements of American shad. Adults utilize well oxygenated (>=5 ppm), flowing water, although they do not appear to have specific preferences for spawning locations other than broad flats and shallow water. Spawning may occur over a variety of substrate types providing water velocity is sufficient enough to keep sedimentation minimal. Spawning generally occurs at water temperatures of 8-26 C with peak activity occurring within the range of 14-21 C. Temperatures for maximum egg hatch and survival is 15.5-26 C. Temperatures at or near 11 C are minimal for egg incubation, and temperatures in excess of 80.1 F are unsuitable. Juvenile shad are found at water temperatures of 10-31 C. Temperatures less than 10 C cannot be tolerated. Juvenile outmigration begins when the water temperature go below 15.5 C.

**General Habitat Preferences:**

- Minimum Elevation (m): 0
- Maximum Elevation (m): 0

**Patch Size Requirements:**

- Prefers large wetland complexes: 
- Prefers large expanses of grassland habitat: 
- Prefers habitat mosaics: 
- Prefers developed landscapes: 
- Prefers actively managed woodland: 
- Requires movement corridors: 
- Prefers large expanses of forest habitat: 

**Vegetation Categories Used:**

(see Appendix B for habitat, community & landscape organization and conservation summaries)

Aquatic: Lower CT River

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

Habitat Fragmentation

Description of habitat problem(s): Spawning success and survival of adults and juveniles are limited by the existence and development of dams and power generation plants which may impede access to spawning and nursery habitats, as well as impose artificial flow regimes associated which in turn alter and degrade habitat for shad. Fishway design deficiencies at ladders on the Connecticut River at Turners Falls, Massachusetts are being examined as likely causes for the significant reduction in shad run abundance into Vermont and New Hampshire. This exacerabtes the habitat fragmentation problem.

**Non-Habitat Problems:**

- Harvest or Collection
- Predation or Herbivory

Description of non-habitat problem(s): Migrating adult and juvenile shad are susceptible to predation,
especially fish predators. Improvements in stock strength of striped bass and bluefish are believed to have increased predatory pressure on migrating clupeid populations, including shad. Being an anadromous species, shad are subjected to a wide variety of problems associated with extensive migrations and residency in both marine and freshwater environments. Excessive commercial harvest off the Atlantic seaboard and within the estuaries represents a problem for shad stocks. Outmigrating adult and juvenile shad may be exposed to turbine mortality at power dams resulting in high mortality.

### Bibliography:

Lake Champlain supports the only population of mooneye in Vermont. This population is on the eastern edge of its continental range. Historic references to the species suggest this fish has never been abundant or common in the lake. Information on the biology and population status of mooneye in Lake Champlain is still generally lacking. It is reported to be sensitive to turbidity and sedimentation.

**Distribution Summary:**
Mooneye is a North American species with a range extending from James Bay, Ottawa River to the Lake Champlain and St Lawrence watershed, southwest of the Appalachian Mountains through western New York and Pennsylvania to Arkansas and Oklahoma, north through eastern Kansas to North Dakota, southeastern Saskatchewan and southern Manitoba (Scott and Crossman 1973). In Vermont, it is a peripheral species at the eastern most extent of its range and has been recorded only from Lake Champlain, including the southern part of the lake, and near the mouths of the Missisquoi and Lamoille rivers and Otter Creek.

**Known Watersheds**
- Lake Champlain Direct
- Lamoille River
- Missisquoi River
- Otter Creek

**Possible Watersheds**
- Winooski River
Mooneye are found in shallow areas of large lakes and deep pools of clear rivers where the bottom is relatively free of silt (Langdon et al. In press). Although it is generally found in non-flowing waters, it may also occur in swift waters, such as below dams (Trautman 1957). Mooneye has rarely been taken with collection gear at depths greater than 10.7 m (Scott and Crossman 1973). The mooneye is a warm water species, preferring water temperatures in the range of 27.5-29.0 C, and migrate up rivers to spawn when the water temperatures reach 19.4 C (Langdon et al. In press).

Habitat Description:

Habitat Information is based on the following:

### Bibliography:

Cisco or Lake Herring
Coregonus artedi
Fish

Conservation Assessment:

Final Assessment: Medium Priority
Global Rank: G5
Global Trend: Unknown
State Rank: S4
State Trend: Unknown
Exirpated in VT? No
Regionally Rare? Yes

Assessment Narrative:

In Vermont, cisco is limited to the deep, cold (oligotrophic) waters of Lake Champlain. It does not appear to be a particularly abundant species in the lake. Relatively little is known about the status of cisco in Lake Champlain, including its abundance and distribution. Limiting factors to the species may be degradation of its habitat, such as alteration of the lake's thermal structure; potential competition with exotics (e.g., alewife) and parasitism by sea lamprey.

Distribution:

This species is the most widely distributed of the 14 species of the genus Coregonus occurring in North America. It is found from eastern Quebec to the Hudson Bay, through the Great Lakes system, Ontario, Manitoba, Saskatchewan and Alberta, north into the Northwest Territories, and in the Mackenzie River system north to Great Bear Lake (Scott and Crossman 1973). In Vermont, where it occurs on the eastern edge of its range, cisco are restricted to Lake Champlain.

Known Watersheds
Lake Champlain Direct

Habitat Description:

Habitat Information is based on the following:

Limited Local Knowledge ✓ Extensive Local Knowledge □ Regional Literature □ General Literature □

In Vermont, cisco inhabit the cold, deep areas of Lake Champlain. This is a schooling, open-water species inhabiting cool mid-lake areas during the summer, shifting to shallower waters inshore from fall to spring. It cannot tolerate water temperatures of over 26.1 C. Cisco spawn in late fall, just prior to ice formation, at depths of about .9-3 m, over gravel to rubble bottom (Langdon et al. In press).
Cisco or Lake Herring

<th>Value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Elevation (m)</td>
<td>29</td>
</tr>
<tr>
<td>Maximum Elevation (m)</td>
<td>29</td>
</tr>
</tbody>
</table>

**Habitat Problems:**

- Climate Change
- Invasion by Exotic Species

**Description of habitat problem(s):**

The appearance of alewife in Lake Champlain is of great concern due to their potential impact through competition with other pelagic planktivores, such as cisco. The species also require deep, cold water. If climate change has a significant impact on the thermal structure of Lake Champlain, this could affect the cisco population.

**Non-Habitat Problems:**

- Competition
- Loss of Prey Base
- Parasites

**Description of non-habitat problem(s):**

Sea lamprey have negatively impacted cisco in other bodies of water (Smith 1985, Bronte et al. 2003). As soft-scaled members of the salmon family, cisco are susceptible to parasitism/predation by sea lamprey. Lamprey predation was identified as a contributing factor to the decline of cisco in Lake Superior (Bronte et al. 2003), and 80% of cisco in Oneida Lake, NY that died off during high summer temperatures had lamprey scars (Smith 1985). So far there are no direct reports of lamprey impacts on cisco in Lake Champlain. Cisco are primarily pelagic (open-water) feeders on zooplankton, and therefore might compete with other species with similar feeding habits, such as smelt. The appearance of alewife in Lake Champlain could pose a problem to both of these native open-water planktivores.

Lake Whitefish
Coregonus clupeaformis
Fish

**Conservation Assessment:**

- **Final Assessment:** Medium Priority
- **Global Rank:** G5
- **Global Trend:** Unknown
- **State Rank:** S4?
- **State Trend:** Unknown
- **Exirpated in VT?** No
- **Regionally Rare?** Yes

**Assessment Narrative:**

In Vermont, lake whitefish are limited to the deep, cold (oligotrophic) waters of Lake Champlain. It does not appear to be a particularly abundant species in the lake. Relatively little is known about the status of lake whitefish in Lake Champlain, including its abundance and distribution. Limiting factors to the species are degradation of its habitat, such as alteration of the lake's thermal structure; potential competition with exotics (e.g., alewife) and parasitism by sea lamprey.

**Distribution:**

Lake whitefish is a widely distributed North American species. Its range includes virtually all of Canada and Alaska, the Great Lakes, the St. Lawrence River including northern New York, Vermont, New Hampshire and Maine (Scott and Crossman 1973). In Vermont, it is confined to Lake Champlain. However, in 1878 lake whitefish were introduced into five other Vermont lakes, such as Lake Dunmore in Addison County and Lake St. Catherine in Rutland County, but none of these introductions were successful (Langdon et al. In press).

**Natural History Elements:**

- **Home Range:** No
- **Migrant?** No
- **Within watershed** ☐
- **Within biophysical region** ☐

- **Within Region** ☐
- **Within US** ☐
- **Outside US** ☐

**Distribution Summary:**

Lake whitefish inhabit cold lakes which are deep and clear. Lake whitefish spawn during November and December at water temperatures below 7.8 °C; spawning occurs near the surface in water less than 7.6 m deep, and the adhesive eggs sink to the bottom onto a usually gravel or rubble and occasionally sand substrate (Langdon et al. In press).
Common Name: Lake Whitefish  
Scientific Name: Coregonus clupeaformis  
Species Group: Fish

**Vegetation Categories Used:**

Aquatic: Lake Champlain

(see Appendix B for habitat, community & landscape organization and conservation summaries)

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

Climate Change

*Description of habitat problem(s):* Lake whitefish also require deep, cold water. If climate change has a significant impact on the thermal structure of Lake Champlain, this could affect the population of lake whitefish.

**Non-Habitat Problems:**

Competition

Parasites

*Description of non-habitat problem(s):* The appearance of alewife in Lake Champlain is of great concern due to their potential impact through competition with other pelagic planktivores, such as lake whitefish. Sea lamprey have negatively impacted lake whitefish in Lake Superior (Bronte et al. 2003). As soft-scaled members of the salmon family, lake whitefish are susceptible to parasitism/predation by sea lamprey. Lamprey predation was identified as a contributing factor to the decline of lake whitefish in Lake Superior (Bronte et al. 2003), and whitefish populations rebounded after implementation of lamprey control.

**Assessment Narrative:**

Very little is known about its status in Vermont waters. Populations have been reported in lakes Seymour, Willoughby and Beaver Pond in Holland, and possibly Holland Pond. The New York State Department of Environmental Conservation plans to conduct research to verify and/or establish secure, abundant and self-sustaining populations of round whitefish in at least five Adirondack lakes. If necessary, remnant stocks of round whitefish will be enhanced through artificial propagation.

**Distribution:**

![Biophysical Regions in Vermont]

**Natural History Elements:**

- **Migrant?** No
- **Within watershed** □
- **Within biophysical region** □
- **Within VT** □
- **Within Region** □
- **Within US** □
- **Outside US** □

**Distribution Summary:**

In Vermont, round whitefish is found in lakes Seymour, Willoughby and in Beaver Pond in Holland. A historic record of "lake whitefish" in Holland Pond (located near Beaver Pond in Holland) is believed actually to have been a round whitefish.

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge ☑
- Extensive Local Knowledge □
- Regional Literature □
- General Literature □

The round whitefish is an inhabitant of cold, clear lakes and rivers. In rivers it occurs over rocky bottoms. In the Great Lakes it is commonly found inshore at depths of less than 36.6 m. It sometimes occurs in brackish waters. The round whitefish is a benthic insectivore, feeding on benthic invertebrates and occasionally fishes and fish eggs. Round whitefish require gravel for spawning. Since eggs incubate overwinter with no parental care, a silt-free spawning substrate probably is essential for successful recruitment as for other salmonids.
Common Name: Round Whitefish

#### Habitat Problems:
- Climate Change
- Habitat Alteration
- Invasion by Exotic Species
- Sedimentation

**Description of habitat problem(s):** This species was once common to many of New York's Adirondack lakes. Recent surveys have shown its distribution there significantly reduced. The New York DEC has speculated on the possible causes: "predation by invading yellow perch on whitefish eggs and fry; predation by smallmouth bass; competition with lake whitefish; over fishing; loss of spawning sites; siltation; and lake acidification". Given the current and past locations in Vermont, only the following causes are possible for Vermont lakes: predation by yellow perch on whitefish eggs and fry (in lakes Seymour and Willoughby); predation by smallmouth bass (Lake Seymour only); loss of spawning sites and siltation (lakes Seymour and Willoughby). Beaver Pond is a small remote pond with no human structures along the shore and only seasonal human use within the watershed. With a low alkalinity (about 4mg/l) lake acidification, however, exists as a potential problem to that population. pH values for beaver Pond have been observed to drop well below 6.0 during spring runoff. Since this species is a benthic insectivore it relies entirely on invertebrates on the bottom as a food source. Loss or reduction of this food through sedimentation would limit its existence. Sedimentation may also limit egg survival by reducing oxygen exchange with surrounding water. Eggs incubate for months unguarded and unmaintained making a low sedimentation rate necessary for egg survival. Loss of spawning sites through siltation is also a threat. Climate change could result in the warming of the coldwater thermal regime that round whitefish require.

#### Non-Habitat Problems:
- Competition
- Loss of Prey Base
- Pollution
- Predation or Herbivory

**Description of non-habitat problem(s):** Beaver Pond is a small remote pond with no human structures along the shore and only seasonal human use within the watershed. With a low alkalinity (about 4mg/l) lake
acidification is a potential threat to that population. Acidification would first impact newly hatched eggs, since this stage is normally the most vulnerable to acidity. Multiple year class failures would result in reductions or possible extermination of the species. Predation on whitefish eggs and fry by yellow perch in lakes Seymour and Willoughby and by smallmouth bass in Lake Seymour is a threat to these populations. Lake whitefish may be a competitor with round whitefish.

New York State Department of Environmental Conservation Website: [http://www.dec.state.ny.us/website/site/subject.html](http://www.dec.state.ny.us/website/site/subject.html)
Atlantic Salmon (anadromous)

Common Name: Atlantic Salmon (anadromous)
Scientific Name: Salmo salar (anadromous)
Species Group: Fish

Conservation Assessment:

Final Assessment: High Priority
Global Rank: G5
State Rank: S4
Extirpated in VT? Yes
Regionally Rare? Yes

Assessment Narrative:

Self-sustaining populations of anadromous Atlantic salmon no longer exist in Vermont. The Connecticut River population is at this time wholly dependent on stocking cultured fry and smolts as part of the Connecticut River Basin Atlantic Salmon Restoration Plan developed by the Connecticut River Atlantic Salmon Commission. The species has also been considered for restoration to the Lake Champlain watershed (see bibliography); however, there is no consensus at this time of the historic presence of anadromous salmon in that basin. Current restoration efforts in Lake Champlain are directed at the landlocked form, although restoration of an anadromous population could be under future consideration.

Distribution:

Known Watersheds
CT-Ashuelot River
CT-Bellows Falls Dam to Vernon Dam
CT-Waits River to White River
CT-White River to Bellows Falls
Deerfield, MA-VT

Possible Watersheds
Lake Champlain Direct
Lamoille River
Missisquoi River
Winooski River

Natural History Elements:

Migrant? Yes
Within watershed
Within biophysical region
Within VT
Within Region
Within US
Outside US

Distribution Summary:

Anadromous Atlantic salmon historically were native to the Connecticut River Basin. In Vermont they ranged from the Massachusetts state line upstream to the Canadian border near Beechers Falls. Whether or not sea-run salmon were native to Lake Champlain is being debated and at this time cannot be substantiated. Further investigation is warranted. Juvenile salmon resulting from extensive stocking inhabit most of the larger watersheds of the Connecticut River Basin; occasionally adult salmon are also found in some of these waters. The stocking effort is part of a multi-state program with the goal to restore anadromous salmon to the basin.
The complex life cycle of the salmon requires spawning and rearing habitat in freshwater streams, migratory habitat in large rivers, coastal estuary environments where salmon smolts adapt from freshwater to saltwater life, and finally North Atlantic ocean environments where salmon spend most of their adult life. For spawning, salmon require streams with sufficient stretches of coarse, clean gravel for building nests and laying eggs. Gravel stretches are often 2-3 meters long and more than one meter wide. Water in spawning areas is swift with depths of 30-60 cm. Streams must have adequate cover, and food supply to sustain young salmon through the first two, sometimes three, years of life. Juvenile salmon utilize a variety of stream habitats depending on life stage and season. They feed on both aquatic and terrestrial invertebrates while using gravel, cobbles and boulders for protective cover. Adult salmon require pools as holding and resting habitat during migration prior to spawning. Salmon spawn in clean gravel areas of rivers or streams that provide a hydraulic head of water through the nest or redd. The optimum location is at the tail of a pool and the head of a riffle or upstream edge of a gravel bar where the water velocity is increasing (Peterson 1978). Redds average 25-50 cm deep and are quite large, about 4.0 m2 in size.

Upon emergence in May or June, salmon fry disperse and establish territories along stream margins and shallow riffles of gravel and cobble (Morantz 1987). Small parr, 4 to 7 cm in length, prefer riffle habitat with a gravel and cobble substrate. Studies by Rimmer et al (1983) indicated the use of pools by salmon parr increased with age and size. Large parr, exceeding 7 cm in length, prefer deeper riffle and run habitat with a cobble-boulder substrate in which particle size exceeds 6.4 cm (Bley 1987). As parr grow, their territories increase in area, forcing them to move to other locations or territories including pool habitat. Parr have been observed moving into ponds and lakes near fluvial streams and rivers as rearing habitat. Calkins (1989) summarized winter habitat requirements for salmon parr. Overall, parr generally stayed in their summer habitat during the autumn and moved into the substrate as the water temperature started to drop below 10 C. Cunjak (1988) documented salmon parr hiding beneath rocks in riffle and run habitats. Large parr and presmolts will use pools and lakes as over-winter habitat. Habitat connectivity is important not only for spawning adults but also for parr which have been found to shift between summer feeding territories and winter habitat (McCormick et al. 1998). It has been inferred that frozen substrate may increase salmon parr mortality in streams. Atlantic salmon smolts leave freshwater and the post-smolts migrate to feeding areas in the North Atlantic during late spring and summer (Hansen and Quinn 1998).

Adult Atlantic salmon require increased river flows and velocities to stimulate upstream migration. Optimum velocities for migration appear to be in the 67 to 128 cm/s range. Vertical barriers such as dams and waterfalls (head > 10 ft) pose significant problems for upstream migration. Adult salmon seek resting pools and large boulders as temporary refuge from swift currents during upstream spawning migration. Optimal holding pools are deep, well shaded pools with cool temperature provided by spring or seeps. Holding pools are characterized by a gravel substrate with large boulders. These pools also provide over-winter refuge for salmon after spawning in autumn.
**Common Name:** Atlantic Salmon (anadromous)

**Current Problems:**  (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Climate Change
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Invasion by Exotic Species
- Sedimentation

**Description of habitat problem(s):** Dams, culverts or other water diversions are serious problems to salmon. They can be barriers to both upstream migrating adults and downstream migration of smolts. Artificial flow regimes associated with hydrogeneration facilities can alter and degrade habitat for salmon. Removing stream buffers can result in habitat loss (loss of cover and increased water temperatures). Dredging or channelization of streams will result in loss and degradation of spawning and rearing habitat for salmon. Soil Erosion can increase stream sedimentation. Sedimentation adversely impacts salmon habitat through the deposition of fine sediment (particle size < .6 cm in diameter) into spawning gravel and cobble/boulder rearing areas. Non-native and exotic species primarily affect juvenile salmon including smolts through a number of factors such as increased predation, competition, and disease risk.

**Non-Habitat Problems:**
- Disease
- Genetics
- Pollution
- Predation or Herbivory
- Unknown Non-Habitat Threats

**Description of non-habitat problem(s):** Genetics considerations are an important factor for salmon restoration in Vermont. Since native salmon extirpated from the Connecticut River watershed, it is extremely important to maintain existing brood stock sources and breeding protocols to protect and enhance genetic diversity. Being an anadromous species, salmon are subjected to a wide variety of problems associated with extensive migrations and residency in both marine and freshwater environments. Upstream
migrating salmon are confronted by passage barriers, such as dams and culverts, and outmigrating fish are often subjected to mortality resulting from passage through power station turbines and/or extended residency times in power impoundments which may make fish physiologically unprepared for life in saltwater or expose smolts to greater freshwater predation pressures. Larger native and non-native fish such as striped bass, walleye, and smallmouth bass in the Connecticut River and possibly other estuary and marine species in Long Island Sound are significant predators of emigrating smolts. Salmon are highly susceptible to diseases primarily through contact with commercial aquaculture salmon in the marine or estuary environments, and fish culture operations in freshwater. Sea lice parasitism can also affect adult salmon. Acid deposition pollution appears to have adverse physiological effects on juvenile salmon especially emigrating smolts. In recent years, there have been more reports of declining salmon populations from many regions within its worldwide range. It is unknown whether this is a short-term downward trend or more of a long-term problem to the species. It is also believed that the water temperature oscillation in the Atlantic Ocean has been a factor in reducing adult salmon returns to home waters in many countries over the past decade.

**Common Name:** Atlantic Salmon (anadromous)
**Scientific Name:** Salmo salar (anadromous)
**Species Group:** Fish

Common Name: Arctic Char or Sunapee Trout
Scientific Name: Salvelinus alpinus oquassa
Species Group: Fish

**Conservation Assessment:**

- **Final Assessment:** High Priority
- **Global Rank:** G5T2Q
- **Global Trend:** Unknown
- **State Rank:** SX
- **State Trend:** Unknown
- **Extirpated in VT?** Yes
- **Regionally Rare?** Yes

**Assessment Narrative:**

The first documented report of arctic char from Vermont was of a fish collected by J. W. Titcomb in 1899 from Little Averill Lake. That fish was placed in the collection of the Smithsonian Institution (USNM 00061723), where it remains to this day. Since that collection and well into the early 1900s arctic char in the Averill lakes are mentioned anecdotally, including articles in some of the popular literature, suggesting that they were then quite common there. However, apart from that single archived specimen, the condition of which defies taxonomic confirmation, no other examples are known to exist in other collections nor have been reported in more recent years from the Averill lakes. Whether or not arctic char ever existed in the Vermont or actually were misidentified lake trout (saibling) is being actively debated. Nonetheless, whatever the outcome of the debate may be, for now the Vermont population is presumed to be extirpated.

**Distribution:**

The species has a circumpolar distribution inhabiting inshore marine waters, lakes, and rivers of the northern hemisphere (Scott and Crossman 1973). In Vermont, arctic char have been reported only from Great and Little Averill Lakes in Essex County. Populations in Vermont are near the southern extent of the species North American range.

**Natural History Elements:**

  - Within US
  - Outside US

**Distribution Summary:**

The species has a circumpolar distribution inhabiting inshore marine waters, lakes, and rivers of the northern hemisphere (Scott and Crossman 1973). In Vermont, arctic char have been reported only from Great and Little Averill Lakes in Essex County. Populations in Vermont are near the southern extent of the species North American range.

**Known Watersheds**

Saint-Francois River

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Arctic char inhabit inshore marine waters, lakes, and rivers (Scott and Crossman 1973). Both anadromous and freshwater (non-migratory) populations exist within its range; however, only the latter form may have occurred...
Common Name: Arctic Char or Sunapee Trout  
Scientific Name: Salvelinus alpinus aquassa  
Species Group: Fish

in Vermont. Non-migratory fish remain in lakes and rivers where they frequent deep runs and pools of medium to large lakes, and rivers (www.fishbase.org). Habitat requirements of arctic char probably do not differ much from those of other related Salvelinus species, including brook trout and dolly varden. All require cold, well oxygenated water. Char spawn over gravel or rocky shoals in lakes, or in quiet pools in rivers, at depths of 1.0-4.5 m (Scott and Crossman 1973).

**General Habitat Preferences:**

- Minimum Elevation (m): 513
- Maximum Elevation (m): 530
- Patch Size Requirements:
  - Prefers large wetland complexes: □
  - Prefers large expanses of grassland habitat: □
  - Prefers habitat mosaics: □
  - Prefers developed landscapes: □
  - Prefers actively managed woodland: □
  - Requires movement corridors: □
  - Prefers large expanses of forest habitat: □

**Vegetation Categories Used:**

Aquatic: Lacustrine

(see Appendix B for habitat, community & landscape organization and conservation summaries)

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Climate Change
- Habitat Alteration
- Habitat Fragmentation
- Sedimentation

*Description of habitat problem(s):* These threats would apply to arctic char if it still occurred in Vermont. See reports for brook trout and lake trout.

**Non-Habitat Problems:**

- Competition
- Genetics
- Pollution
- Predation or Herbivory

*Description of non-habitat problem(s):* Arctic char are very sensitive to water pollution (www.fishbase.org). The population that once existed in the Averill lakes is suspected of having been eliminated following the introduction of lake trout and the resulting predation on arctic char.
Common Name: Arctic Char or Sunapee Trout  
Scientific Name: Salvelinus alpinus oquassa  
Species Group: Fish

Common Name: Brook Trout (naturally reproducing populations)  
Scientific Name: Salvelinus fontinalis (naturally reproducing pops)  
Species Group: Fish

**Conservation Assessment:**

**Final Assessment:** Medium Priority  
**Global Rank:** G5  
**State Rank:** S5  
**Global Trend:** Unknown  
**State Trend:** Unknown  
**Extirpated in VT?** Unknown  
**Regionally Rare?** Unknown

**Assessment Narrative:**

Brook trout is the most widely distributed and abundant salmonid species indigenous to Vermont. Today, wild, stocked and mixed populations occur throughout the state. Brook trout is sensitive to pollution and habitat degradation. Deforestation, water development and pollution, habitat degradation, and competition and/or predation from introduced fishes all have taken a toll on wild populations throughout its natural range. Beginning around the mid 1800s and continuing to the present time brook trout have been cultured in hatcheries and stocked to restore fishable populations to many waters throughout the state. Fish culture programs have relied upon brook trout strains from multiple sources most of which have originated from populations outside of Vermont. Strains may very well have been selected for characteristics other than their adaptability and survival in Vermont environments, but rather for their performance in hatcheries (e.g., survival and growth potential) and sport fishing qualities. The ability of hatchery trout to survive in Vermont waters beyond the first season after release has been evaluated with results indicating multi-season survival is generally poor. In many respects our established self-sustaining wild brook trout populations may have certain advantages over traditional hatchery strains in certain situations, such as greater adaptability to Vermont environments. In recent years other states within the natural range of the species have been investigating wild populations to identify heritage (native) brook trout strains. Research into the existence of heritage strains in Vermont has not been pursued. The extensive stocking of hatchery strains on top of wild populations throughout the state over the past 150 years raises doubts that any heritage strains can be identified with acceptable certainty. Therefore, the fallback position is conservation of all wild naturally reproducing brook trout populations in the state.

**Distribution:**

![Biophysical Regions in Vermont](image)

**Natural History Elements:**

- **Home Range:**
  - Migrant? Yes
  - Within watershed: Yes
  - Within biophysical region: No
  - Within VT: No
  - Within Region: No
  - Within US: No
  - Outside US: No

**Distribution Summary:**

The brook trout is native to most of eastern Canada from Newfoundland to west of Hudson Bay; south in the Atlantic, Great lakes and Mississippi River basins to Minnesota and through the Appalachian Mountains to Georgia (Page and Burr 1991). It has been introduced widely outside of its natural range. In Vermont, the species is distributed throughout the state where suitable habitat is available and competing species are absent or low in abundance.
**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Brook trout occur in headwater streams, small to medium rivers, and lakes and ponds where waters are clear, cool and well-oxygenated. Raleigh (1982) gives a comprehensive review of brook trout habitat requirements. Riverine brook trout habitat is characterized by being influenced by cold-springs, having silt-free rocky substrate in riffles and runs, well vegetated stream banks, abundant instream cover, and relatively stable stream flows, temperatures and stream banks. Lacustrine habitats are typically oligotrophic in character. The temperature range for brook trout is 0-24 C, with optimal temperatures for growth and survival in the range of 11-16 C. Warm water temperatures appears to be the single most critical factor influencing brook trout survival and production. Brook trout normally require high dissolved oxygen concentrations, optimally near saturation or >= 7 mg/L at temperatures <=15 C and >= 9 mg/L at temperatures >= 15 C. Instream and riparian cover is recognized as an important component of brook trout habitat. Brook trout tends to be more tolerant of low pH water than other salmonid species. Most spawning occurs in stream habitat, although brook trout may spawn directly in lakes and ponds where there are upwellings.

### General Habitat Preferences:

<table>
<thead>
<tr>
<th>Minimum Elevation (m): 0</th>
<th>Maximum Elevation (m): 0</th>
</tr>
</thead>
</table>

### Vegetation Categories Used:

- Aquatic: Fluvial
- Aquatic: Lacustrine

### Current Problems:

(see Appendix C for definitions of problem categories)

#### Habitat Problems:

- Climate Change
- Habitat Alteration
- Habitat Fragmentation
- Sedimentation

**Description of habitat problem(s):** Brook trout habitat has been degraded by alterations of natural stream channel morphology and flow regimes; water pollution; fragmentation (e.g., dams and culverts); reduction of riparian vegetation resulting in stream water temperature increases and loss of instream cover (e.g., large woody debris) Spawning habitat and trout egg and fry survival are negatively affected by sedimentation. Climate change could potentially degrade temperature regimes required by brook trout throughout its distribution.

#### Non-Habitat Problems:
Brook Trout (naturally reproducing populations)

**Scientific Name:** Salvelinus fontinalis (naturally reproducing pops)

**Species Group:** Fish

---

**Description of non-habitat problem(s):** Brook trout compete poorly with introduced salmonids, such as brown and rainbow trout, as well as warmwater species (e.g., centrachids, percids and esocids). Additionally, these competitors may prey upon brook trout. Stocking of non-native brook trout strains on wild populations may result in inbreeding, loss of genetic characteristics necessary for species survival, and intra-specific competition. Stocking also puts heritage populations at risk of introducing disease causing pathogens, such as whirling disease.

**Assessment Narrative:**

Even though a large number of lakes in Vermont are being managed for lake trout fisheries, with a few exceptions most of these waters do not support self-sustainig populations but depend on the stocking of hatchery-reared fish. Currently, six lakes are being managed for self-sustaining lake trout populations: Big and Little Averill ponds, Averill; Maidstone lake, Maidstone; Echo Lake, Charleston; Caspian Lake, Greensboro; and Crystal Lake, Barton. Restored naturally reproducing, self-sustaining lake trout populations within the species natural range in the state warrant special conservation attention.

- Home Range: Yes
- Migrant? Yes
  - Within watershed: Yes
  - Within biophysical region: No
  - Within VT: No
  - Within Region: No
  - Within US: No
  - Outside US: No

**Distribution Summary:**

The natural occurrence of lake trout is limited to North America. Its natural range closely aligns with the limits of the Pleistocene glaciation. In Vermont, the species has been stocked extensively throughout the state; however, with perhaps very few exceptions these populations are not self-sustainable and are completely dependent on continued stocking for the populations to exist. The few self-sustaining populations in Vermont are all located in the Northeast Kingdom: Big and Little Averill ponds, Averill; Maidstone lake, Maidstone; Echo Lake, Charleston; Caspian Lake, Greensboro; and Crystal Lake, Barton (L. Gerardi, Vermont Fish and Wildlife Department, personal communication). Natural reproduction has been documented in Lake Champlain, but that population is not at the present time sustainable without stocking.

**Known Watersheds**

- Saint-Francois River
- Upper Connecticut
Lake Trout (naturally reproducing populations)
Salvelinus namaycush (naturally reproducing pop)
Fish

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Lake trout is a species of oligotrophic lakes. In the southern part of their range the species inhabits deep, cold lakes whereas at more northern latitudes they are also found in shallow and deep waters. This species is intolerant of waters with low oxygen content, and prefers cold water, seeking areas with temperatures below 16°C (Langdon et al. In press). Lake trout spawn over rocky shoals and along wave-swept shorelines. Spawning in riverine habitat is rare. Lake trout can spawn in depths of water from .3-61 m over gravel that measures 3.8-10.2 cm in diameter, typically aggregating in the fall over clean substrate, with deep interstitial spaces (Langdon et al. In press). Lake trout prefer eating small crustaceans, insects, and fish. Young lake trout eat plankton, insects, and small aquatic invertebrates.

**General Habitat Preferences:**

- Minimum Elevation (m): 288
- Maximum Elevation (m): 530

**Vegetation Categories Used:**

Aquatic: Lacustrine
Aquatic: Lake Champlain

**Current Problems:**

Lake trout are susceptible to habitat degradation, such as lake eutrophication, hypolimnion oxygen depletion, spawning shoal sedimentation, lake level manipulations. Introduced species, such as alewives, are known to contribute to reproductive failure by disruption of thiamine metabolism in lake trout. Sea lamprey in Lake Champlain predate on lake trout and may be a significant factor in population declines there. Dams constructed at lake outlets raise lake levels that can erode shoreline soils, increasing sedimentation of spawning shoals and decreasing reproductive success. Water level fluctuations, associated with water storage for hydropower, may result in dewatered lake trout egg and embryos, also negatively impacting reproductive success.

**Non-Habitat Problems:**
Common Name: Lake Trout (naturally reproducing populations)
Scientific Name: Salvelinus namaycush (naturally reproducing pop)
Species Group: Fish

Genetics
Harvest or Collection
Parasites

Description of non-habitat problem(s): Lake Maidstone contains a population of lake trout (a.k.a. locally as lunge) that is morphologically distinct from lake trout in all other Vermont lakes. It is possible that this population is genetically distinct and represents a unique population that is native to Vermont. Because it is unknown whether this population is genetically distinct, no strategies exist to protect this population. Lake trout are highly valued by anglers due to the large size that this species can attain. Overfishing could result in the loss of self-sustaining, native lake trout populations (Ellrott and Marsden 2004).

**Bibliography:**

Common Name: Redfin Pickerel
Scientific Name: Esox americanus
Species Group: Fish

**Conservation Assessment:**

**Final Assessment:** Medium Priority

- **Global Rank:** G5
- **State Rank:** S4
- **Extirpated in VT?** No
- **Regionally Rare?** No

**Assessment Narrative:**

In Vermont, the redfin pickerel has a limited distribution. Populations have been found in rivers and streams and associated wetlands primarily limited to the lower Champlain Valley. Very little is known about its biology and specific habitat requirements within the state. Redfin pickerel spawning habitat is vulnerable to alteration or degradation. The species is potentially threatened by hybridization with other esocid species introduced to its waters.

**Distribution:**

**Natural History Elements:**

- **Home Range:** Unknown
- **Migrant?** No
- **Within watershed** ☐
- **Within biophysical region** ☐
- **Within VT** ☐
- **Within Region** ☐
- **Within US** ☐
- **Outside US** ☐

**Distribution Summary:**

The redfin pickerel (Esox americanus americanus) is the subspecies restricted to eastern United States; the grass pickerel (E. a. vermiculatus) is the western subspecies. Redfin pickerel is a fish primarily associated with the eastern coastal plain. It is distributed from the St. Lawrence River (Lac St. Pierre) south through the Richelieu-Champlain-Hudson system into New York, east through southern Vermont and New Hampshire to Long Island and south along the coastal plain to Georgia (Scott and Crossman 1973). In Vermont, redfin pickerel appears to be limited to the Poultney-Castleton rivers drainage, South Fork of East Creek in Orwell, and Pond Brook in Monkton.

**Known Watersheds**

Lake Champlain Canal

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge ✓
- Extensive Local Knowledge ☐
- Regional Literature ☐
- General Literature ☐

The redfin pickerel occurs in weedy areas of lakes, ponds and slow rivers. The redfin is often found in tea-colored, acidic waters with pH values as low as 4.3. The redfin pickerel spawns during April and May when water temperatures reach 10 C (Langdon et al. in press). Adults congregate to spawn and adhesive eggs are
**Common Name:** Redfin Pickerel  
**Scientific Name:** *Esox americanus*  
**Species Group:** Fish

Broadcast randomly in heavily vegetated, shallow areas along lakeshores or streambanks. Young redfins first consume zooplankton, snails and crustaceans, switching to fish as they grow older. Adults feed on fish and crayfish, but may supplement these food items with small crustaceans and insects (Jenkins and Burkhead 1993). This species may play a significant role in fish community structure because of its preference to predate on fish.

**General Habitat Preferences:**
- Minimum Elevation (m): 0
- Maximum Elevation (m): 0

**Patch Size Requirements:**
- Prefers large wetland complexes: 
- Prefers large expanses of grassland habitat:
- Prefers habitat mosaics:
- Prefers developed landscapes:
- Prefers actively managed woodland:
- Requires movement corridors:
- Prefers large expanses of forest habitat:

**Vegetation Categories Used:**
- Aquatic: Fluvial
- Aquatic: Lacustrine

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

*Description of habitat problem(s):* Loss or alteration (i.e. through flow alteration, dewatering, sedimentation) of vegetated, shallow areas along lakeshores or streambanks would pose a problem to the reproductive success of the species.

**Non-Habitat Problems:**

*Description of non-habitat problem(s):* This species has a limited distribution in Vermont, located in 3 drainages. If any of these populations undergo a reduction in population size (i.e., population bottleneck), then it is possible that genetic variation will be lost, forfeiting the evolutionary potential of the species. Natural selection can only act in the presence of genetic variation, and, therefore, the higher the genetic variability in a population, the higher the likelihood for population persistence. If gene flow between the 3 populations is limited, then the genetic variability of each population could decrease over time. Also, redfin pickerel have been reported to hybridized with northern pike and chain pickerel (Jenkins, 1993), which poses further genetic concerns. The introduction of northern pike or chain pickerel to waters populated by redfin pickerel poses the risk of hybridization, as well as introduce inter-specific predation and competition for habitat and forage. Decreased genetic variation in redfin pickerel would hinder the ability of the populations to adapt to changing conditions over time.

**Bibliography:**

In Vermont, currently there are only two recognized populations in the state. One population at least until recent years occurred in a stretch of the Missisquoi River between the Swanton and Highgate Falls dams. This is believed to be the only remaining native population in Vermont. The status of this population is much in doubt, although investigations continue and periodically there are reports of angler caught musky in this river section. The other population is in northern Lake Champlain, including the lower accessible reaches of the Missisquoi River below Swanton dam and possibly other large tributaries to the lake. Fish observed in the lake are of undetermined origin. Muskellunge of the Chautauqua strain are stocked by New York Department of Environmental Conservation into the Big Chazy River, a tributary to northern Lake Champlain. Similarly the Vermont Fish and Wildlife Department stocked musky into Otter Creek and the Lemon Fair River for a few years (1980-84) without evidence of successful population establishment. Whether or not fish now observed in the lower Missisquoi River are of wild, stocked or mixed origin is unknown at this time. In 2002, muskellunge was proposed for state endangered species designation; however, the recommendation was not adopted by the Secretary of the Agency of Natural Resources at that time.
The muskellunge is a fish of warm, heavily vegetated lakes; stumpy, weedy bays; and slow, heavily vegetated rivers (Scott and Crossman 1973). In late winter and early spring (shortly after ice-out), they migrate into marshes to spawn in clear, shallow water having abundant aquatic and/or immersed terrestrial vegetation (Trautman 1957). The range of spawning temperatures is 9.4-15 C with an optimum temperature of 12.8 C. Eggs are distributed in shallow water (38-51 cm deep) with abundant vegetation (Scott and Crossman 1973). Adults return to deep water after spawning. After the eggs hatch, the fry remain in the shallow water but move out into deeper habitat as the water recedes from flooded areas. Optimum water temperature for muskellunge is 25.6 C, although temperatures up to 32.2 C can be withstood, and apparently low dissolved oxygen levels can be tolerated (Scott and Crossman 1973).

**Known Watersheds**

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation

**Description of habitat problem(s):** Habitat conversion, such as draining of wetlands and berming of floodplains for agriculture and land development, limit the species by eliminating critical spawning and nursery habitats. The construction of dams and other fish passage obstruction fragment muskellunge habitat and deny fish access to spawning areas (e.g., Swanton dam on the Missisquoi River). In the case of Swanton dam, any muskellunge still residing in the river upstream of the dam are isolated from the Lake Champlain population.
Esox masquinongy

**Common Name:** Muskellunge  
**Scientific Name:** Esox masquinongy  
**Species Group:** Fish

### Non-Habitat Problems:
- Disease
- Genetics
- Harvest or Collection
- Pollution
- Predation or Herbivory

**Description of non-habitat problem(s):** The sizes of the native Lake Champlain and Missiquoi River muskellunge populations are unknown at this time. If adult numbers are extremely small, the loss of genetic variability may limit the native population. Additionally, stocking of Chautauqua strain muskellunge into the Big Chazy River, New York by NYDEP and the possibility for these fish to spawn with any native fish could alter genetic characteristics and introduce undesirable traits. In turn, the loss of genetic variation and/or introduction of deleterious traits could weaken the ability of the native population to survive or to be ultimately restored to its historic waters in Vermont. One disease of particular note is lymphosarcoma which was first detected in northern Lake Champlain northern pike in 2002 (T. Jones, Vermont Fish and Wildlife Department, personal communication). Wolf (1988) reports that of the two esocid species the muskellunge is more sensitive to this viral infection than northern pike. To date no muskellunge from Lake Champlain or the Missisquoi River have been tested for lymphosarcoma. Buchanan and Lebeau (2000) suggest several pollution sources to Lake Simcoe, Ontario, Canada as indirect impacts on muskellunge spawning and nursery habitats. Phosphorus loading from natural sources, accelerated erosion and point sources. It has been reported that northern pike spawn earlier than muskellunge, such that pike fry are large enough to prey upon muskellunge fry.

<tr>
<td>Regionally Rare?</td>
<td>No</td>
<td></td>
</tr>
</tbody>
</table>

**Assessment Narrative:**

The status and limiting factors to brassy minnow in Vermont are little known. Populations in the state have been identified in Little Otter Creek, Pond Brook (Colchester) and two Missisquoi River tributaries. One of the known populations in Vermont occurs in a low gradient stream which flows through lands under dairy use, such as streamside grazing and barnyard runoff. This suggests brassy minnow may be a tolerant species; however, this in itself does not explain the apparent limited distribution of the species within the Champlain Valley biophysical region. Vermont populations are on the eastern edge of the species North American range.

### Distribution:

![Biophysical Regions in Vermont](image)

### Natural History Elements:

- **Home Range:** Unknown
- **Migrant?** No
- **Within watershed**
- **Within biophysical region**
- **Within VT**
- **Within Region**
- **Within US**
- **Outside US**

### Distribution Summary:

This North American species ranges from the upper St. Lawrence River and Lake Champlain region west through southern Ontario and Michigan, west through the Arkansas and Missouri rivers to Colorado, Wyoming and Montana, north to Alberta, and in the Fraser and Peace rivers in British Columbia (Scott and Crossman 1973). In Vermont, it has only been found at few locations in the upper Missisquoi River watershed, Pond Brook in Colchester, and Little Otter Creek. Vermont populations are on the eastern edge of the species North American range.

### Known Watersheds

- Lake Champlain Direct
- Missisquoi River

### Habitat Description:

Habitat Information is based on the following:

- **Limited Local Knowledge**
- **Extensive Local Knowledge**
- **Regional Literature**
- **General Literature**

The brassy minnow is most commonly found in pools of cool, slow-flowing, tea-colored streams and small rivers. It may also occur in lakes and ponds but rarely in high numbers. The preferred bottom material is mud.
and organic debris but can also be found over sand and gravel. In Vermont, this species has been found over gravelly bottoms as well as mud and silt. Critical habitat for the brassy minnow is not clearly defined. The five Vermont occurrences (three drainages) are from low gradient streams. Since two of the five known records of occurrence in Vermont are from drainages that support high proportion of agricultural activities, it seems that this fish may not be particularly sensitive to impacts caused by barnyard runoff, intensive grazing or row crops. The literature reports the brassy minnow having a preference for slow boggy waters with soft bottoms; however, three out of the four Vermont occurrences are from non-bog (clear) streams with hard bottoms. They are considered to be a pool species and were found inhabiting pool habitats at all four sites in Vermont. In the Great Plains of the U.S. brassy minnows have been reported to withstand summertime water temperatures exceeding 90 F and dissolved oxygen levels less than 0.2 ppm when in isolated pools of small streams. It is not know whether Vermont populations are as hardy as their western counterparts. It is not a food specialist, being herbivorous to omnivorous. Adhesive eggs are laid on a variety of substrates including logs, rocks and plants.

**General Habitat Preferences:**
- Minimum Elevation (m): 0
- Maximum Elevation (m): 200
- Patch Size Requirements:
  - Prefers large wetland complexes: ☐
  - Prefers large expanses of grassland habitat: ☐
  - Prefers habitat mosaics: ☐

Vermont Department of Fish and Wildlife  
Comprehensive Wildlife Conservation Strategy  
Species Assessment Report

Common Name: Bridle Shiner  
Scientific Name: Notropis bifrenatus  
Species Group: Fish

Conservation Assessment:

**Final Assessment:** High Priority  
**Global Rank:** G5  
**Global Trend:** Unknown

**State Rank:** S1?  
**State Trend:** Unknown

**Extirpated in VT?** No  
**Regionally Rare?** Yes

Assessment Narrative:

No abundance trend data exists for Vermont populations; however, it is considered rare and/or a species in decline throughout much of its range, including Connecticut, Delaware, Maine, Maryland, Massachusetts, New York, North Carolina, Pennsylvania, Quebec, Rhode Island, South Carolina, and Virginia (Honeyfield and Ross 2004). Bridle shiner is reported to be extirpated from North and South Carolina, and disappearing from watersheds throughout most of its range (Sabo 2000). In Vermont, nine populations have been identified. With exception to the population reported to be in Lake Memphremagog, all populations are in the Lake Champlain watershed. Bridle shiner is a species sensitive to habitat degradation and alteration. Increased sedimentation and turbidity have been specifically identified as limiting factors. Reduction in aquatic plants either through water quality degradation or herbicide treatments also put the species at risk. Habitat lacking adequate refuge cover increase populations to predation.

Distribution:

This North American species occurs in the Atlantic drainage from southern Maine to Virginia, west through Lake Champlain to New York and the Lake Ontario basin (Scott and Crossman 1973). In Vermont, bridle shiner are found in Lake Champlain, several other locations within that watershed, and has been reported to occur in Lake Memphremagog.

Known Watersheds:
- Lake Champlain Canal
- Lake Champlain Direct
- Mississquoi River
- Otter Creek

Possible Watersheds:
- Saint-Francois River

Natural History Elements:

**Home Range:** Migrant? No

- Within US  
- Outside US

Distribution Summary:

This North American species occurs in the Atlantic drainage from southern Maine to Virginia, west through Lake Champlain to New York and the Lake Ontario basin (Scott and Crossman 1973). In Vermont, bridle shiner are found in Lake Champlain, several other locations within that watershed, and has been reported to occur in Lake Memphremagog.
The bridle shiner is a species of quiet streams, lakes and ponds (Scott and Crossman 1973, Page and Burr 1991). Honeyfield and Ross (2004) describe its habitat as slow, warm backwater eddies of low gradient streams and ponds with dense vegetation and substrate of mud, sand or gravel. Spawning occurs in areas of calm water, at a depth of about two feet, and in openings within stands of dense emergent aquatic vegetation (Cornell web site). Holms et al. (1999) suggest bridle shiner require open water above aquatic plant stands to spawn. The species has a strong preference for clear water necessary for this daytime, sight-feeder to forage on prey organisms (Honeyfield and Ross 2004). It is tolerant of brackish water but is not acid tolerant (Holm et al. 1999).

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge ✗ Extensive Local Knowledge ✓ Regional Literature ✓ General Literature ✓

The bridle shiner is a species of quiet streams, lakes and ponds (Scott and Crossman 1973, Page and Burr 1991). Honeyfield and Ross (2004) describe its habitat as slow, warm backwater eddies of low gradient streams and ponds with dense vegetation and substrate of mud, sand or gravel. Spawning occurs in areas of calm water, at a depth of about two feet, and in openings within stands of dense emergent aquatic vegetation (Cornell web site). Holms et al. (1999) suggest bridle shiner require open water above aquatic plant stands to spawn. The species has a strong preference for clear water necessary for this daytime, sight-feeder to forage on prey organisms (Honeyfield and Ross 2004). It is tolerant of brackish water but is not acid tolerant (Holm et al. 1999).

**General Habitat Preferences:**

- Minimum Elevation (m): 0
- Maximum Elevation (m): -1
- Patch Size Requirements:

  - Prefers large expanses of forest habitat: ❏

**Vegetation Categories Used:**

- Aquatic: Fluvial
- Aquatic: Lacustrine
- Aquatic: Lake Champlain
- Aquatic: Large Lake Champlain Tribs Below Falls

(see Appendix B for habitat, community & landscape organization and conservation summaries)

**Current Problems:** *(see Appendix C for definitions of problem categories)*

**Habitat Problems:**

- Habitat Alteration
- Habitat Fragmentation
- Invasion by Exotic Species
- Sedimentation

**Description of habitat problem(s):** Threats include stream channelization, erosion, point-source discharges, loss of riparian vegetation, and large-scale development all have been identified as practices that have been identified as practices that have increased turbidity and altered bridle shiner habitat where the species have become extirpated (Sabo 2000). Sedimentation and siltation are suspected as being major factors for the decline of bridle shiner in the Delaware River Basin (Honeyfield and Ross 2004). They also suggest the species may be vulnerable to highway construction activities which alter bridle shiner habitat including streamflow regimes, channel structure, water quality, and aquatic plant abundance. Being a sight-feeder turbid water conditions interfere with bridle shiner feeding and suppresses the growth of aquatic vegetation on which the fish is dependent for feeding, reproduction and cover (Holm et al. 1999). They also identify the spread of Eurasian milfoil as a potential problem to the species. This plant can alter the composition of the plant community by replacing native vegetation and invading the entire water column thereby eliminating clear water areas above the plants that are necessary for spawning (Sabo 2000).
**Common Name:** Bridle Shiner  
**Scientific Name:** Notropis bifrenatus  
**Species Group:** Fish

### Non-Habitat Problems:
- Genetics
- Pollution
- Predation or Herbivory

**Description of non-habitat problem(s):** Scott and Crossman (1973) state bridle shiner are an important forage species for pickerel as well as other piscivorous fishes (yellow perch, smallmouth bass, crappie) where these species co-exist. In some New England lakes and ponds, where significant reduction or removal of submerged aquatic plant stands has occurred, fish predators (e.g., bass) have decimated bridle shiner populations (Sabo 2000). Honeyfield and Ross (2004) state, that within the species range populations appear to be highly fragmented and declining with separation distances between known populations exceeding 200 km. They suggest this may have resulted in genetic divergence among populations, although this has not been investigated. This species is sensitive to sedimentation and chemical runoff from agricultural lands (Ontario's Biodiversity website). The bridle shiner is not tolerant of acidic water making it vulnerable to atmospheric deposition (Holm et al. 1999).

<td>High Priority</td>
<td>State Rank: S1</td>
<td>State Trend: Unknown</td>
</tr>
<tr>
<td>Extirpated in VT?</td>
<td>No</td>
<td>Regionally Rare? No</td>
</tr>
</tbody>
</table>

**Assessment Narrative:**

The blackchin shiner has a very limited distribution in Vermont in that it is primarily restricted to the southern Lake Champlain watershed (5 identified populations) and a couple sites (2 populations) in the northern part of the watershed. Where it is found, the blackchin shiner does not occur in high abundance. This species is sensitive to habitat degradation and alteration. Increased sedimentation and turbidity have been specifically identified as limiting factors. Reduction in aquatic plants either through water quality degradation or herbicide treatments also put the species at risk. Habitat lacking adequate refuge cover increase populations to predation.

**Distribution:**

**Natural History Elements:**

- **Home Range:**
  - No
  - Migrant? No
  - Within watershed
  - Within biophysical region
  - Within VT
  - Within Region
  - Within US
  - Outside US

**Distribution Summary:**

This North American species occurs only in the Great Lakes basin, the upper Mississippi River drainage, and downstream through the St. Lawrence River drainage into western Quebec (Scott and Crossman 1973). In Vermont, the species on the eastern edge of its distribution and if limited to a few locations within the Lake Champlain watershed.

**Known Watersheds**

- Lake Champlain Canal
- Lake Champlain Direct

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Trautman (1957) describes the blackchin shiner as a fish of glacial lakes and streams characterized by having very clear water, substrate of clean sand, gravel or organic debris, and the presence of dense beds of submersed vegetation. Scott and Crossman (1973) also note the species' preference for quiet pools in streams and weedy inshore areas of lakes. This shiner is also found in inlet and outlet streams of lakes (Becker 1983).
Scott and Crossman (1973) state "clear, clean, weedy waters are essential for the survival of the blackchin shiner," but little information has been reported on spawning site preference and behavior. This species is an indicator of good water quality.

**General Habitat Preferences:**
- Minimum Elevation (m): 0
- Maximum Elevation (m): 200
- Patch Size Requirements:
  - Prefers large wetland complexes: 
  - Prefers large expanses of grassland habitat: 
  - Prefers habitat mosaics: 
  - Prefers actively managed woodland: 
  - Requires movement corridors: 
  - Prefers large expanses of forest habitat: 

**Vegetation Categories Used:**
- Aquatic: Fluvial
- Aquatic: Lacustrine
- Aquatic: Lake Champlain
- Aquatic: Large Lake Champlain Tribs Below Falls
- Aquatic: Man-Made Water Bodies

**Current Problems:**  (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Invasion by Exotic Species
- Sedimentation

**Description of habitat problem(s):** The blackchin shiner is intolerant of silt. Trautman (1957) notes that it has disappeared from Ohio waters once they became turbid, silt covered the bottom, and the aquatic vegetation disappeared. The continuing expansion of the submersed exotic weed Eurasian milfoil in Vermont's lakes and ponds threatens blackchin shiner populations. Milfoil may displace native plant communities and alter the composition and fish habitat value of the aquatic plant community. Additionally the propensity for this invasive plant to establish dense beds impairing the use of some lakes for boating, swimming and fishing has resulted in the increased use of herbicides. Significant reduction in aquatic plant abundance could degrade habitat necessary for this species. One such herbicide in common use in Vermont is fluridone (Sonar). The Michigan Environmental Science Board has concluded that this broad spectrum herbicide will not only control Eurasian milfoil but also significantly impact native aquatic plant species when applied at the labeled rate (Premo et al. 1999). Significant reduction in milfoil beds can subject blackchin shiner populations to increased predation pressure before native aquatic plants become reestablished restoring cover habitat for the shiner.

**Non-Habitat Problems:**
- Predation or Herbivory

**Description of non-habitat problem(s):** The blackchin shiner does not appear to be particularly abundant in any of the waters it is known to occur in Vermont. Aggressive aquatic plant control activities in these waters could significantly reduce this important refuge habitat and subject the shiner populations to increased predation.
**Common Name:** Blackchin Shiner  
**Scientific Name:** Notropis heterodon  
**Species Group:** Fish

</table>

Assessment Narrative:

The number of known blacknose shiner populations in Vermont is eight with all but one of these being in the Lake Champlain watershed. It has also been reported from Springfield Reservoir in Windsor County. Whether or not this single collection (one specimen) represents a population as removed as it is from other populations in the state is questionable. Blacknose shiner is a species sensitive to habitat degradation and alteration. Increased sedimentation and turbidity have been specifically identified as limiting factors. Reduction in aquatic plants either through water quality degradation or herbicide treatments also put the species at risk. Habitat lacking adequate refuge cover increase populations to predation.

Distribution Summary:

The blacknose shiner is a widely distributed species occurring from the Hudson Bay drainage to the New England states west to Iowa (Scott and Crossman 1973). In Vermont, it appear to be most frequently encountered in the Lake Champlain watershed, albeit there are a few occurrences from other locations within the state.

### Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

The blacknose shiner is a species of clear, shallow water habitats in glacial lakes and small streams (Scott and Crossman 1973). Most recorded occurrences in Vermont (11 out of 13 records) have come from riverine habitats (R. Langdon, Vermont Department of Environmental Conservation, personal communication). The species does not appear to have any particular preference for substrate type, although Trautman (1957) states it has been found in waters with bottoms comprised of sand, gravel, muck, peat or organic debris. The presence of submersed vegetation is an important component of blacknose shiner habitat (Page and Burr 1991, Trautman 1957). Backlund (1995) reports the fish requires cool well-oxygenated water. This species is intolerant of sedimentation and turbid water (Backlund 1995, Eddy and Underhill 1974, Trautman 1957). This species is an important indicator of pristine, high quality waters (Backlund 1995). The biology and detailed habitat requirements of the blacknose shiner apparently have either been not thoroughly investigated or reported. Backlund (1995) states that the blacknose shiner is a host fish for the freshwater mussel cylindrical papershell Anodontoides ferussacianus, a state listed endangered species in Vermont.

### General Habitat Preferences:

- **Minimum Elevation (m):** 0
- **Maximum Elevation (m):** -1
- **Patch Size Requirements:**
  - Prefers large wetland complexes: ☑
  - Prefers large expanses of grassland habitat: ☑
  - Prefers habitat mosaics: ☑
  - Prefers developed landscapes: ☑
  - Prefers actively managed woodland: ☑
  - Requires movement corridors: ☑
  - Prefers large expanses of forest habitat: ☑

### Vegetation Categories Used:

- **Aquatic: Fluvial**
- **Aquatic: Large Lake Champlain Tribs Below Falls**

### Current Problems:  
(see Appendix C for definitions of problem categories)

#### Habitat Problems:

- Invasion by Exotic Species
- Sedimentation

**Description of habitat problem(s):** Backlund (1995) states the blacknose shiner is intolerant of turbid, polluted waters and that in South Dakota it has disappeared from many streams due to sedimentation, loss of aquatic vegetation and food, water temperature increases, and lowered dissolved oxygen. Aquatic plant control also poses a problem to blacknose shiner populations. In Minnesota the removal of aquatic vegetation along lake shorelines and increase sedimentation and turbidity levels have reduced this species (Eddy and Underhill 1974).

#### Non-Habitat Problems:

- Pollution
- Predation or Herbivory
Common Name: Blacknose Shiner  
Scientific Name: Notropis heterolepis  
Species Group: Fish

**Description of non-habitat problem(s):** The blacknose shiner is reported to be intolerant of water pollution (Backlund 1995). Elimination of aquatic plant beds can expose this species to increased predation.

**Assessment Narrative:**

In Vermont, the quillback is only known to occur in Lake Champlain and the lower reaches of a few of the lake's larger tributaries. It is rarely encountered and little is known of its abundance and habitat use within the lake. Historic accounts for this species in the suggest it has never been abundant there (Greeley 1930, VFGD 1963). Apparently little is known about this species biology, habitat requirements, and vulnerabilities which may shed light on reasons for its relative rarity in the state.

**Distribution:**

**Natural History Elements:**

- **Home Range:** Unknown  
- **Migrant:** Yes  
- **Within watershed:** ✓  
- **Within biophysical region:** □  
- **Within VT:** □  
- **Within Region:** □  
- **Within US:** □  
- **Outside US:** □

**Distribution Summary:**

This North American species occurs east from the St. Lawrence River south along the eastern seaboard to the Roanoke River in Virginia; west of the Appalachian Mountains through New York south to Alabama, west to Oklahoma, through eastern Kansas and the Dakotas, and west to central Alberta (Scott and Crossman 1973). In Vermont, quillbacks are limited to Lake Champlain and a few of the lake's larger tributaries as far upstream as the fall line (i.e., Missisquoi, Lamoille, Winooski rivers). The Vermont population is on the eastern edge of its North American range.

**Known Watersheds**

Lake Champlain Direct  
Lamoille River  
Missisquoi River  
Winooski River
The quillback is a demersal species inhabiting pools, backwaters and main channels of low gradient creeks to large rivers with substrate of sandy silt or sandy muck; they as well occur in lakes (Page and Burr 1991; Trautman 1957). Trautman (1957) also reported quillback inhabiting dredged ditches less than 3 m in width. During spawning season (April and May) quillback migrate to spawning areas, such as into streams and overflow areas at river bends or bays in lakes, where the eggs are randomly broadcast over sand or mud bottom substrate in quiet water (Scott and Crossman 1973). Quillback habitat ranges from clear lacustrine waters to turbid waters.

**General Habitat Preferences:**

| Minimum Elevation (m): | 0 |
| Maximum Elevation (m): | 45 |

**Vegetation Categories Used:**

- Aquatic: Lacustrine
- Aquatic: Lake Champlain
- Aquatic: Large Lake Champlain Tribs Below Falls

**Current Problems:**

**Habitat Problems:**

- Unknown Habitat Threats

  **Description of habitat problem(s):** Very little is known about quillback biology (Scott and Crossman 1973), therefore it can be surmised that habitat problems are equally not well understood.

**Non-Habitat Problems:**

- Reproductive Traits
- Unknown Non-Habitat Threats

  **Description of non-habitat problem(s):** Life history traits may be limiting but are unknown.

Species Assessment Report

Common Name: Silver Redhorse
Scientific Name: Moxostoma anisurum
Species Group: Fish

Conservation Assessment:

Final Assessment: High Priority
Global Rank: G5
State Rank: SU
Extirpated in VT? No
Regionally Rare? Unknown

Assessment Narrative:

Vermont records indicate silver redhorse are found in Lake Champlain and the Poultney and Missisquoi rivers. Little is known about the species biology and habitat within these waters. Based on published accounts the species is vulnerable to habitat alteration, degradation and fragmentation. In Vermont, the species is on the eastern edge of its North American range.

Distribution:

Natural History Elements:

Home Range:
Migrant? Yes
Within watershed
Within biophysical region
Within VT
Within Region
Within US
Outside US

Distribution Summary:

A North American species which occurs east from the St. Lawrence River, south through central New York, southwest through the western half of the coastal states to northern Alabama, northwest through eastern Arkansas and Missouri, north through North Dakota, and into Saskatchewan and Alberta (Scott and Crossman 1973). In Vermont, the silver redhorse is on the eastern edge of its North American range and occurs only in Lake Champlain and up to the fall line in the Missisquoi and Poultney rivers.

Known Watersheds

Lake Champlain Direct
Missisquoi River

Habitat Description:

Habitat Information is based on the following:

Limited Local Knowledge ☑ Extensive Local Knowledge ☐ Regional Literature ☐ General Literature ☐

The silver redhorse is found in small to moderately-sized rivers and occasionally lakes. In rivers it prefers deep pools with some current (Meyer 1962). During their first year of life silver redhorses sometimes remain in small streams where they were hatched. This species avoids silty bottoms and may also be intolerant to general environmental degradation (Langdon et al. In press). Adult silver redhorse perform annual migrations to
spawn. Seasonal movement patterns may prove important for successful spawning. Silver redhorse are early spawners and in their southern range breed from April through early May in water temperatures of 11-15 C. Spawning usually occurs in shallow riffles over gravel and cobble (Jenkins and Burkhead 1993). Silver redhorse feed on insect larvae, microcrustaceans, mollusks, algae, detritus, crayfishes, and the fry of shiners (Jenkins and Burkhead 1993).

**General Habitat Preferences:**

- Minimum Elevation (m): 29
- Maximum Elevation (m): 45
- Requires movement corridors:  
  - Prefers large wetland complexes:  
  - Prefers large expanses of grassland habitat:  
  - Prefers habitat mosaics:  
  - Prefers developed landscapes:  
  - Prefers actively managed woodland:  
  - Requires movement corridors:  
  - Prefers large expanses of forest habitat:  

**Vegetation Categories Used:**

- Aquatic: Lake Champlain
- Aquatic: Large Lake Champlain Tribs Below Falls

(see Appendix B for habitat, community & landscape organization and conservation summaries)

**Current Problems:**  (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Habitat Alteration
- Habitat Fragmentation
- Sedimentation

**Description of habitat problem(s):** Flow alteration, temperature alteration, or decreased habitat diversity (i.e. loss of deep pool habitat) will most likely have negative effects for different life stages of silver redhorse. Fragmentation of silver redhorse habitat may disrupt the seasonal movement patterns of this species. For example, these movement patterns may prove critical for successful reproduction, and therefore the completion of the species life cycle. Disruption to the spawning efforts of this species poses a problem to population viability (i.e. weak year classes over time compound negative influences and population declines). If the quantity or quality of silver redhorse habitat is limited in a system, then interconnected river reaches will prove necessary for this species to find and occupy optimal or suitable habitat. Loss of riparian vegetation, general construction activity, road maintenance activities (ditching, sanding), bridge and culvert construction, agriculture, timber harvest, dam failure, rapid drawdown of dam impoundments, streambank erosion, and shifts in channel form or location are sources of sediment for silver redhorse habitat. Controlling sediment input into streams may be crucial to prevent detrimental effects to silver redhorse, because sedimentation decreases the quality and quantity of optimal habitat (i.e. spawning, feeding) for this species. Sedimentation eliminates interstitial spaces which could be critical for egg deposition and development and for production of benthic organisms, such as aquatic insects, a source of food for silver redhorse. Sedimentation has been shown to cause loss or reduction in fish populations, and disrupt the feeding and reproductive activities of fishes (Berkman and Rabeni, 1987).

**Non-Habitat Problems:**

- Pollution
**Common Name:** Silver Redhorse  
**Scientific Name:** Moxostoma anisurum  
**Species Group:** Fish

**Description of non-habitat problem(s):** Water pollution may indirectly influence silver redhorse through negative impacts to its prey base. Depletion of food items will negatively affect species growth and survival.

Assessment Narrative:

Vermont records indicate shorthead redhorse are found only in Lake Champlain and several of its larger tributaries. It is the more common of the three redhorse species occurring in the state. Virtually little is known about the species biology and habitat within these waters. Based on published accounts the species is vulnerable to habitat alteration, degradation and fragmentation. In Vermont, the species is on the eastern edge of its North American range.

Distribution:

The shorthead redhorse is the most widely distributed of the redhorse species in North America. It occurs from the upper St. Lawrence River, south into the Lake Champlain drainage to the coast in New York, east of the Appalachian Mountains to South Carolina, west through Pennsylvania and Ohio, southwest into Indiana and Arkansas, the Tennessee River drainage in Alabama, west to Texas, northwest through eastern Colorado and Montana, north to central Alberta, east to southern Hudson Bay and the east shore of James Bay (Scott and Crossman 1973). In Vermont, the species is on the eastern edge of its North American range and is confined to Lake Champlain and several large tributaries up to the fall line.

Distribution Summary:

The shorthead redhorse is the most widely distributed of the redhorse species in North America. It occurs from the upper St. Lawrence River, south into the Lake Champlain drainage to the coast in New York, east of the Appalachian Mountains to South Carolina, west through Pennsylvania and Ohio, southwest into Indiana and Arkansas, the Tennessee River drainage in Alabama, west to Texas, northwest through eastern Colorado and Montana, north to central Alberta, east to southern Hudson Bay and the east shore of James Bay (Scott and Crossman 1973). In Vermont, the species is on the eastern edge of its North American range and is confined to Lake Champlain and several large tributaries up to the fall line.
Habitat Description:

This species prefers the clear water of small to large rivers and sometimes lakes. Most individuals have been observed holding or feeding in deep pools. It is found over clean sand, gravel, and cobble substrate, and is tolerant of water temperatures up to 37 C. It requires a silt-free habitat and is thought to be susceptible to many forms of water pollution (Langdon et al. In press). It is common to find this species living in the same areas as other redhorse species. In Vermont, the shorthead redhorse is restricted to the larger tributaries of Lake Champlain (Langdon et al. In press). The spawning period for shorthead redhorse occurs in spring from early April to early July, as influenced by local regional conditions (i.e. climate). Spawning water temperature is 11-21 C. Spawning occurs in slow and moderate runs and pools over large gravel (Jenkins and Burkhead 1993). Shorthead redhorse may perform spawning migrations to find optimal spawning habitat. Spawning groups of this species have been observed in streams where adults are normally not found except during breeding time (Jenkins and Burkhead 1993). Seasonal movement patterns may prove important for successful spawning. Shorthead redhorse is specialized to benthically feed on aquatic insects, small crustaceans, mollusks, algae, and detritus (Jenkins and Burkhead 1993). Highly silted or embedded substrate may preclude this species from consuming its preferred food items. Studies have shown that the principal, insect food items of redhorses are chironomids, ephemeropterans, and trichopterans (Meyer 1962).

General Habitat Preferences:

Minimum Elevation (m): 29
Maximum Elevation (m): 45

Patch Size Requirements:

Requires movement corridors:
Prefers large wetland complexes:
Prefers large expanses of grassland habitat:
Prefers habitat mosaics:
Prefers actively managed woodland:
Requires movement corridors:
Prefers large expanses of forest habitat:

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:

Habitat Alteration
Habitat Fragmentation
Sedimentation

Description of habitat problem(s): Flow alteration, temperature alteration, or decreased habitat diversity (i.e. loss of deep pool habitat) will most likely pose negative effects for different life stages of shorthead redhorse. For instance, shallow, channel margin habitats that are indicative of slower velocities are important for young redhorses. Anthropogenic flow alteration has been shown to alter and limit this habitat, affecting juvenile life stages (Scheidegger and Bain, 1995). Fragmentation of shorthead redhorse habitat may disrupt the seasonal movement patterns of this species. For example, these movement patterns may...
Vermont Department of Fish and Wildlife
Comprehensive Wildlife Conservation Strategy
Species Assessment Report

Common Name: Shorthead Redhorse
Scientific Name: Moxostoma macrolepidotum
Species Group: Fish

prove critical for successful reproduction, and therefore the completion of the species life cycle. Disruption to the spawning efforts of this species poses a problem to population viability (i.e. weak year classes over time compound negative influences and population declines). If the quantity or quality of shorthead redhorse habitat is limited in a system, then interconnected river reaches will prove necessary for this species to find and occupy optimal or suitable habitat. Loss of riparian vegetation, general construction activity, road maintenance activities (ditching, sanding), bridge and culvert construction, agriculture, timber harvest, dam failure, rapid drawdown of dam impoundments, streambank erosion, and shifts in channel form or location are sources of sediment for shorthead redhorse habitat. Controlling sediment input into streams may be crucial to prevent detrimental effects to shorthead redhorse, because sedimentation decreases the quality and quantity of optimal habitat (i.e. spawning, feeding) for this species. Sedimentation eliminates interstitial spaces which could be critical for egg deposition and development and for production of benthic organisms, such as aquatic insects, a source of food for shorthead redhorse. Sedimentation has been shown to cause loss or reduction in fish populations, and disrupt the feeding and reproductive activities of fishes (Berkman and Rabeni, 1987).

Non-Habitat Problems:

Pollution

Description of non-habitat problem(s): Water pollution may indirectly influence shorthead redhorse through negative impacts to its prey base. Depletion of food items will negatively affect species growth and survival.

**Protect and restore in-stream and riparian habitats via water quality, flow and temperature improvements; sediment reduction; streamside buffers; and maintenance of in-stream habitat structure (e.g., large woody debris, deep pools).**

**Bibliography:**

Vermont records indicate greater redhorse are found in northern Lake Champlain and the Missiquoi River. Virtually little is known about the species biology and habitat within these waters. Nonetheless, based on published accounts the species is vulnerable to habitat alteration, degradation and fragmentation. In Vermont, the species is on the eastern edge of its North American range.

The greater redhorse inhabits medium to large rivers, large lakes and impoundments. It prefers coarse substrate, such as gravel, cobble, and boulders in clean water. In rivers, this species is frequently found in moderate to swift current in run or riffle habitat and may also be found in large river pools. Generally, it is not found in silty areas and is believed to be intolerant of silt and turbidity (Jenkins and Burkhead 1993). Spawning occurs in spring or summer in high velocity riffle habitat over gravel or cobble substrate that is silt free. Spawning has been found to occur in moderate stream velocities (3.8-116.9 cm/s) and at shallow depths.
Greater Redhorse

**Moxostoma valenciennesi**

(10-100 cm) (Healy 2002). Greater redhorse may perform annual migrations upstream to spawn and downstream after spawning. In an Ontario river, this species was observed dispersing up to 15 km downstream from its spawning habitat (Healy 2002). This species demonstrates important seasonal movement patterns. Different life stages have specific habitat preferences. Age-0 fish were found in shallow (20 cm), slow velocity pools (21 cm/s). Juvenile fish (greater than age-0 but not sexually mature) were found in slightly deeper pools (60-149 cm) and higher velocities (37 cm/s) (Healy 2002). The greater redhorse is a specialized benthic feeder such that highly silted or embedded substrate may preclude this species from consuming its preferred food items.

**Current Problems:**  
(see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Habitat Alteration
- Habitat Fragmentation
- Sedimentation

**Unknown Habitat Threats**

**Description of habitat problem(s):** Flow alteration, temperature alteration, or low habitat diversity (i.e., loss of deep pool habitat, shallow riffles, or large woody debris due to human-induced change) will most likely pose negative effects for different life stages of greater redhorse. For instance, shallow channel margin habitats that are indicative of slower velocities are important for young redhorses. Flow alteration has been shown to alter and limit this habitat for juvenile life stages (Scheidegger and Bain 1995). Fragmentation of greater redhorse habitat may disrupt the seasonal movement patterns of this species. For example, these movement patterns may prove critical for successful reproduction, and therefore the completion of the species life cycle. Viability of greater redhorse populations most likely depends on optimal habitat availability (i.e., optimal or suitable depths, velocities, substrate, temperature, and flow regimes). Some evidence suggests that greater redhorse presence and abundance are correlated with longer contiguous river reaches (Healy 2002). If the quantity and quality of greater redhorse habitat is limited in a system, then interconnected river reaches will prove necessary for this species to find and occupy optimal or suitable habitat. Loss of riparian vegetation, general construction activities, road maintenance activities (ditching, sanding), bridge and culvert construction, agriculture, timber harvest, dam failure, rapid drawdown of dam impoundments, streambank erosion, and shifts in channel form or location are sources of sediment into greater redhorse habitat. Controlling sediment input into streams may be crucial to prevent detrimental effects to greater redhorse, because sedimentation decreases the quality and quantity of optimal...
habitat (i.e., spawning, feeding) for this species. Sedimentation eliminates interstitial spaces which could be critical for egg deposition and development and for production of benthic organisms, a primary food source for greater redhorse. Specialized benthic feeders, such as greater redhorse, represent a very ecologically vulnerable group to increased sedimentation, because they are unable to modify their feeding habits. Sedimentation has been shown to cause loss or reduction in fish populations, and disrupt the feeding and reproductive activities of fish (Berkman and Rabeni 1987). The greater redhorse seems to be rare over the majority of its range (Healy 2002). Determining the primary mechanism behind this trend is a challenge. Unknown habitat problems may exist.

Non-Habitat Problems:

Pollution

*Description of non-habitat problem(s):* The reproductive strategy of the greater redhorse is a crucial aspect to its conservation. It becomes sexually mature at a late age, is highly fecund, and spawns seasonally. Disruption to the spawning efforts of this species poses a problem to population viability (i.e., week year classes over time compound negative influences and population declines). Water pollution may indirectly influence greater redhorse through negative impacts on its prey base. Depletion of food items will negatively affect species growth and survival.

Bibliography:

Common Name: Stonecat  
Scientific Name: Noturus flavus  
Species Group: Fish

Conservation Assessment:

Final Assessment: High Priority  
State Rank: S1  
State Trend: Declining

Assessment Narrative:

The stonecat is a state listed endangered species in Vermont with two known populations in the state. One population occurs in a very short section of the river encompassing habitat immediately below and above the fall line. Population monitoring suggests the population has been declining due to unidentified causes. The other population was only recently discovered (October 2004) in Hungerford Brook, a tributary of the Missisquoi River. Little in currently known about the distribution and abundance of stonecat in that stream which warrants further investigation. Both populations is particularly vulnerable to habitat alteration and degradation. In Vermont, the species is on the eastern edge of its North American range.

Distribution:

known watersheds

Lake Champlain Direct

Natural History Elements:

Home Range: Unknown  
Migrant? No  
Within watershed  
Within biophysical region  
Within VT  
Within Region  
Within US  
Outside US

Distribution Summary:

This is a North American species with a distribution described by Scott and Crossman (1973) as the St. Lawrence River and tributaries in Quebec, south in the Hudson, Allegheny and Mohawk systems in New York, west to the Appalachian Mountains, to western North Carolina and northern Alabama (Tennessee River), north through central Tennessee, west through northern Missouri, Kansas and northeastern Colorado, Wyoming to Alberta, east through North Dakota into Manitoba, southeast through the tip of Lake Superior to central Michigan, and into southern Ontario and Quebec (Scott and Crossman 1973). Only two populations of stonecat is known to occur in Vermont. One population is located within a relatively short reach of the LaPlatte River immediately above and below the fall line; and the second is in Hungerford Brook, a tributary of the Missisquoi River. In Vermont, the species is on the eastern edge of its North American range.
The stonecat prefers moderate currents of medium to large rocky-bottomed streams. It is absent, however, from high gradient streams with fast currents. It is also found in lakes near gravel shoals where the current is produced by wave action. The stonecat appears to require a current to prosper, since it has been eliminated from streams where flows have been slowed by the construction of dams. It appears to be intolerant to siltation and general habitat degradation. The stonecat is a state listed endangered species in Vermont with one known population in the state. This population is in a very short section of the river encompassing habitat immediately below and above the fall line. Population monitoring suggests the population has been declining due to unidentified causes. It appears from the literature and Vermont data from the LaPlatte River that this species requires moderate current and a low silt, coarse substrate. Stonecat prefer to use large cobble and boulders for hiding. The combination of habitat requirements of low silt, moderate current, and large substrate represent a somewhat restrictive combination within the Champlain Valley biophysical region.

**General Habitat Preferences:**
- Minimum Elevation (m): 29
- Maximum Elevation (m): 45
- Requires movement corridors:  
- Prefers large wetland complexes:  
- Prefers large expanses of grassland habitat:  
- Prefers habitat mosaics:  
- Prefers developed landscapes:  
- Prefers actively managed woodland:  
- Requires movement corridors:  
- Prefers large expanses of forest habitat:  

**Vegetation Categories Used:**
- (see Appendix B for habitat, community & landscape organization and conservation summaries)
- Aquatic: Fluvial
- Aquatic: Large Lake Champlain Tribs Below Falls

**Current Problems:**
- Habitat Alteration
- Sedimentation

**Description of habitat problem(s):** It has been reported that this species is sensitive to siltation but the exact mechanism of impact is not known. It may be that siltation covers the developing eggs; however, this may not be a problem, since parents are cavity nesters, preparing the nest and providing care for the young. Or, siltation may embed coarse substrate materials eliminating cover habitat and nesting sites. Since in Vermont the stonecat is only found in the LaPlatte River and Hungerford Brook, a primary conservation consideration is the limiting of upstream land use activities that increase siltation in moderate gradient habitats.

**Non-Habitat Problems:**
- Genetics
Species: Noturus flavus
Common Name: Stonecat
Scientific Name: Noturus flavus
Species Group: Fish

Description of non-habitat problem(s): Stonecat is a benthic insectivore, specializing in aquatic insects. Excess sedimentation can impact aquatic insects populations and reduce this species' food base. This species would have difficulty shifting to non-benthic foods. Because stonecat has one of the most restricted distributions of any other fish species in Vermont, reductions in population size causing a bottleneck which could possibly result in a loss of genetic variation forfeiting the evolutionary potential of the species. Natural selection can only act in the presence of genetic variation, and therefore, the higher the genetic diversity in a population, the higher the likelihood for population persistence. If gene flow is limited to within one population of stonecat (estimated number probably much less than 100 individuals), the species is not prepared to adapt to environmental changes of time.

### Bibliography:

Common Name: Redbreast Sunfish
Scientific Name: Lepomis auritus
Species Group: Fish

Conservation Assessment:

Final Assessment: Medium Priority
Global Rank: G5
State Rank: S4
Extirpated in VT? No
Regionally Rare? No

Assessment Narrative:

At this time the redbreast sunfish is not listed as endangered or threatened in any New England state nor has it been federally listed. In Canada, it only occurs in New Brunswick (at the northern extreme of its distribution) and has been designated as a species at risk by the Committee on the Status of Endangered Wildlife. Very little is known about the limiting factors detrimental to this species in Vermont. Its spotty distribution in the state and that it is encountered relatively infrequently even within the waters where it is known to occur warrants investigating the status of these populations, evaluation of its habitat, and identification of possible limiting factors.

Distribution:

Natural History Elements:

Home Range: Migrant? No
Within watershed
Within biophysical region
Within VT
Within Region
Within US
Outside US

Distribution Summary:

The redbreast sunfish occurs along the Atlantic Slope from New Brunswick to Florida. It is also found in Gulf Coast drainages in Georgia and Florida, north into Kentucky and Arkansas. In Vermont, redbreast sunfish are found in the Connecticut River and lakes Morey and Fairlee (Orange County) and the Black River (Windsor County). Historically, the species has been recorded from New York waters within the Lake Champlain drainage (e.g., Lake George and its outlet, the Mettawee River and Little Chazy River) (Greeley 1930); however, no records, past or present, are known from Lake Champlain.

Le
pomis auritus
Redbreast Sunfish

Species Group: Fish

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

This species inhabits the shores of lakes and ponds, and pools of clear streams with little current, but unlike other Vermont sunfishes it is more of a stream-adapted species. Aho and Terrell (1986) report cover, current velocity, and variables correlated with velocity (e.g., gradient, riffle/pool ratios) to be major factors determining the distribution and abundance of redbreast sunfish in riverine systems. Both juveniles and adults are usually found in shallow water near cover, although fish may occupy deeper habitats under warmwater summer conditions and during winter. Important cover include fallen trees, stumps and aquatic vegetation. These hard structures appear to be important habitat components for spawning site selection. Additionally, hard structures have been attributed to being the substrate producing more than 60% of the food organisms consumed by sunfish species, including redbreast sunfish. Scarola (1973) states redbreast sunfish can be found over gravelly bottoms with or without vegetation; however, unlike the pumpkinseed, it does not rely as much on there being aquatic vegetation present. Aho and Terrell (1986) quantify variables critical to habitat suitability models in both lotic and lentic environments for redbreast sunfish. Water temperatures regarded as suitable for growth and survival of adult and juvenile fish are assumed to be in the range of 15-35 °C; for spawning and incubation the optimal range is assumed to be 21.1-27.2 °C. Nests are generally constructed at depths less than 1.5 m. Water velocities at nest sites are less than 0.06 m/s with an average of 0.02 m/s. Based on available information for other sunfish species, 25-70% hard structure cover is estimated to be most productive for redbreast sunfish. This species appears to require a mixture of coarse sand and gravel substrate at spawning sites to be successful.

### General Habitat Preferences:

- **Minimum Elevation (m):** 0
- **Maximum Elevation (m):** 0
- **Patch Size Requirements:**
  - Prefers large wetland complexes: ☐
  - Prefers large expanses of grassland habitat: ☐
  - Prefers habitat mosaics: ☐
  - Prefers developed landscapes: ☐
  - Prefers actively managed woodland: ☐
  - Requires movement corridors: ☐
  - Prefers large expanses of forest habitat: ☐

### Vegetation Categories Used:

- Aquatic: Fluvial
- Aquatic: Lacustrine
- Aquatic: Lower CT River

### Current Problems:

(see Appendix C for definitions of problem categories)

**Habitat Problems:**

Habitat Alteration

*Description of habitat problem(s):* Abundance of hard structures for cover are critical components of redbreast sunfish habitat. Removal of such cover or inadequate structure being recruited into lakes and streams (e.g., from forested riparian areas) may negatively affect the suitability of habitat for this species. It may be sensitive to acidity (i.e., long term pH values <4.0 ), but is tolerant of high temperatures (<35 °C) (Aho and Terrell 1987). Rapid reductions in water level of more than 0.9 m during the spawning season may adversely affect embryo development and survival (Aho and Terrell 1987).
Common Name: **Redbreast Sunfish**  
Scientific Name: **Lepomis auritus**  
Species Group: **Fish**

**Non-Habitat Problems:**

Pollution

*Description of non-habitat problem(s):* Aho and Terrell (1987) identify several potential threats to this species. Low to moderate turbidity levels are suitable to this species; however, excessive levels may impact fish growth and abundance. Pesticide contamination of waters supporting redbreast sunfish has been a suspected cause for the observed decline of some populations.

**Conservation Assessment:**

- **Final Assessment:** High Priority
- **Global Rank:** G3
- **Global Trend:** Unknown
- **State Rank:** S1
- **State Trend:** Unknown
- **Extirpated in VT?** No
- **Regionally Rare?** Yes

**Assessment Narrative:**

In Vermont, the eastern sand darter is a state listed threatened species. All identified populations occur below the Lake Champlain fall line in the Missisquoi, Lamoille, Winooski and Poultey rivers. One exception is the recent collection of the species above the fall line on the Winooski River. Populations are at some risk due to the use of lampricides to control sea lamprey in Lake Champlain and tributaries. Other limiting factors are sedimentation of habitat, deteriorating water quality and flow regime alterations, such as associated with hydroelectric power generation facilities.

**Distribution:**

Eastern sand darters range from the St. Lawrence River drainage, southern Quebec, Vermont and New York; through the Great lakes and Ohio River basins from western New York to eastern Illinois; and south to Kentucky (Page and Burr 1991). In Vermont, populations are known to occur below the fall line in the Missisquoi, Lamoille, Winooski, and Poultey rivers. There is one recent occurrence of the species being collected from above the fall line on the Winooski River. One individual has also been collected in Lake Champlain at the mouth of the Lamoille River in Malletts Bay. In Vermont, this species is on the eastern edge of its range.

**Distribution Summary:**

Eastern sand darters range from the St. Lawrence River drainage, southern Quebec, Vermont and New York; through the Great lakes and Ohio River basins from western New York to eastern Illinois; and south to Kentucky (Page and Burr 1991). In Vermont, populations are known to occur below the fall line in the Missisquoi, Lamoille, Winooski, and Poultey rivers. There is one recent occurrence of the species being collected from above the fall line on the Winooski River. One individual has also been collected in Lake Champlain at the mouth of the Lamoille River in Malletts Bay. In Vermont, this species is on the eastern edge of its range.
The eastern sand darter shows a strong preference for sandy areas of rivers and streams with slow to moderate currents, where it spends most of its time burrowed into the sand with only its eyes or head protruding. It has also been reported from sandy shoals in Lake Erie, but has not been reported in Lake Champlain, except for one individual at the mouth of the Lamoille River in Malletts Bay. The eastern sand darter requires medium to fine sand, so water velocity and sedimentation are important factors in habitat suitability. Habitat use and preference studies indicate that the fish use areas with a large percentage of sand particles 0.23 to 1 mm in size. It is quite sensitive to sedimentation and poor water quality.

### Current Problems:

**Habitat Problems:**

Habitat Alteration

Sedimentation

*Description of habitat problem(s):* The range of the eastern sand darter is believed to be shrinking due to the loss of clean sand habitat caused by increased siltation from soil erosion and agricultural activities. Hydroelectric power generation should be regulated to maintain suitable flows and habitat.

*Description of non-habitat problem(s):* The Lake Champlain Fish and Wildlife Management Cooperative is currently involved in a sea lamprey control program that includes the use of lampricides to kill stream resident lamprey larvae. Bioassay LCD levels on eastern sand darter have determined.

- **Outside US**

**Distribution Summary:**

This is a wide ranging species but is highly localized in the St. Lawrence, Great Lakes and Mississippi River drainages from southern Quebec and Vermont, south to northern Louisiana; along the Gulf Slope in Mobile, Pascagoula and Pearl River drainages (Page and Burr 1991). In Vermont, the species is on the eastern edge of its range with populations known to occur below the fall line in the Winooski, LaPlatte and Poultney rivers. There is a historic record from Lake Champlain on the New York side (Greeley 1930); however, no occurrences have been made within the Vermont portion of the lake.

**Known Watersheds**

- Lake Champlain Canal
- Lake Champlain Direct
- Winooski River
Habitat Description:

The channel darter is a bottom dweller of gravelly or sandy shoals of warm lakes and rivers. In rivers, it is found in areas with coarse sand and gravel substrate. These areas have low to moderate current, but enough water velocity to prevent silt deposition. Channel darters are found in areas with substrates composed of gravel and sand. Preferred habitat is low in sediments and turbidity. Some studies of spawning in rivers and aquaria indicate that channel darters require swift currents (0.03-0.04 m/sec) presumably with gravel substrate.

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:

Habitat Alteration
Sedimentation

Description of habitat problem(s): Channel darters are limited by the loss of clean gravel substrate resulting from increased siltation and turbidity from soil erosion and agricultural activities. Alteration of river flow regimes from hydroelectric power generation may also degrade habitat quality.

Description of non-habitat problem(s): The Lake Champlain Fish and Wildlife Management Cooperative is currently involved in a sea lamprey control program that includes the use of lampricides to kill stream resident lamprey larvae.

**Bibliography:**

Common Name: **Sauger**  
Scientific Name: **Sander canadense**  
Species Group: **Fish**

### Conservation Assessment:

**Final Assessment:** High Priority  
**Global Rank:** G5  
**Global Trend:** Unknown  
**State Rank:** S4S5  
**State Trend:** Unknown  
**Exirpated in VT?** No  
**Regionally Rare?** Yes

**Assessment Narrative:**

In Vermont, sauger occur only in Lake Champlain, where generally they are believed to be more abundant in the southern portion of the lake than northern. Anderson (1978) reported sauger to be present in all sections of the lake except for the Main Lake. While similar to the walleye in appearance and biology, this species has attracted little attention in Vermont and, therefore, little is known about its population here. It has been reported to have been more frequently encountered in the past than at the present time based on general observations made during ice fishing creel surveys (C. Mackenzie, Vermont Department of Fish and Wildlife, personal communication). Sauger have declined in abundance and distribution across its North American range (Rawson and Scholl 1978; Hesse 1994; Pegg et al. 1977).

### Distribution:

**Biophysical Regions in Vermont**

#### Natural History Elements:

- **Home Range:** Unknown  
- **Migrant?** Yes  
- **Within watershed** ✅  
- **Within biophysical region** □  
- **Within VT** □  
- **Within Region** □  
- **Within US** □  
- **Outside US** □

**Distribution Summary:**

The distribution of sauger in North America is from the St. Lawrence-Lake Champlain system south, west of the Appalachian Mountains to Tennessee River in Alabama, southwest to northern Louisiana, northwest through eastern Oklahoma to central Montana and central Alberta east below James Bay to Quebec (Scott and Crossman 1998). The distribution of sauger in Vermont is limited to Lake Champlain, where it may have been more numerous in the southern portion of the lake. Anderson (1978) reported sauger to be present in all sections of the lake except for the Main Lake.

**Known Watersheds**

Lake Champlain Canal
Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Many of the general habitat requirements are similar between sauger and walleye; however, sauger habitat preferences are for large, shallow sections of lakes which are turbid with colloidal clay suspension, as well as large, turbid, slow-flowing rivers (Anderson 1978; Scott and Crossman 1978). Scott and Crossman (1978) considered sauger "less adaptable" than walleye because of these preferences. Walleye and sauger may utilize the same shoals or gravel to rubble in large turbid lakes for spawning (Scott and Crossman 1978). Preferred spawning habitats are shallow shoreline and shoals of lakes and riffles in rivers, including areas immediately below dams providing there is rocky substrate and good water circulation from wave action and river currents (McMahon et al. 1984). Sauger have been found to be highly selective for spawning sites and in some parts of their range have been shown to be reliant on access to a few discrete areas in large tributaries (Nelson 1968; Gardner and Steward 1987; Penkal 1992; Jaeger 2004). Sauger fry must reach their initial feeding grounds within 3-5 days before yolk-sac absorption or they will perish from lack of food (McMahon et al. 1984).

General Habitat Preferences:

- Minimum Elevation (m): 29
- Maximum Elevation (m): 45
- Patch Size Requirements:
  - Prefers large wetland complexes: 
  - Prefers large expanses of grassland habitat: 
  - Prefers habitat mosaics: 
  - Prefers developed landscapes: 
  - Prefers actively managed woodland: 
  - Requires movement corridors: 
  - Prefers large expanses of forest habitat: 

Vegetation Categories Used:

Aquatic: Lake Champlain
Aquatic: Large Lake Champlain Tribes Below Falls

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:

- Habitat Alteration
- Habitat Fragmentation
- Invasion by Exotic Species

Description of habitat problem(s): Sauger are considered to be the most migratory percid and are heavily dependent throughout their life history on unimpeded access to a wide diversity of physical habitats (Collette 1977; Jaeger 2004). The historic spawning grounds of sauger in Lake Champlain are not well known. Undoubtedly, dams have decreased their accessibility to many of the historical spawning grounds in the basin. For example, recent lake sturgeon and walleye habitat assessments conducted on the Missisquoi River indicate most of the quality spawning habitat occurs above Swanton Dam (Madeline Lyttle, U. S. Fish and Wildlife Service, personal communication). Sauger also appear to be sensitive to changes in water quality. Sauger may be more dominant than walleye under very turbid water conditions where they co-occur; however, dominance may shift with changing water quality (Scott and Crossman 1998).
Sander canadense

**Common Name:** Sauger  
**Scientific Name:** Sander canadense  
**Species Group:** Fish

Improvements in Lake Champlain water quality may explain the perceived reduction in sauger abundance, but this needs to be investigated.

### Non-Habitat Problems:

**Competition**

**Description of non-habitat problem(s):** The sauger population was once abundant in portions of Lake Champlain and were captured in considerable numbers as recently as the 1980s. Recent surveys of the South Bay, where sauger were formerly abundant, failed to produce even in a single capture. Predation by native species, such as smallmouth bass (Johnson and Hale 1977) have been found to influence recruitment of walleye, a close relative to sauger, in natural systems (as referenced in Quist et al. 2003). Others have speculated that native piscivorous predators, such as northern pike, smallmouth bass, lake trout, burbot and Atlantic salmon, can be a major source of mortality for age-0 walleye in Lake Champlain (Frater 2002). We would expect these interactions to be as important, if not more so, for sauger. For example, the introduction of black crappie in Black Lake (New York) was believed to have caused successive walleye year-class failures (Schiavone 1983). While black crappie are believed to be native to Lake Champlain, its cogener the white crappie is not. It too has been found to be a significant walleye fry predator in some systems (Quist et al. 2003). White crappie are known to occur in large numbers in areas where sauger were historically abundant, e.g. South Bay (David Nettles, U.S. Fish and Wildlife Service, personal communication). Another exotic in Lake Champlain, the white perch, has been found to be an important predator of walleye eggs (Roseman et al. 1996; Schaeffer and Margraf 1987). White perch have become or are becoming one of the most dominant species in the fish assemblage in some areas of the lake, e.g. Missisquoi Bay (Pierre Bilodeau, Quebec Parks and Wildlife, personnel communication).

</table>
This group consists of several species, the habitat requirements of which vary within the general wetland category. Most species have not been assigned state status ranks, due to incomplete distribution and abundance information, but records for each are very limited. Habitats given for each species refer primarily to reproduction and nymphal requirements; adults of many species require various nearby terrestrial habitats as well. There is some taxonomic uncertainty in Vermont regarding Lestes disjunctus australis.

Southern Spreadwing (Lestes disjunctus australis) Still water habitats (ponds, swamps, backwaters, bogs, vernal pools)
Subarctic Bluet (Coenagrion interrogatum) Boggy sloughs
Citrine Forktail (Ischnura hastata) Marshy ponds, vernal pools, stream backwaters, seeps
Comet darner (Anax longipes) Vernal pools and semi-permanent ponds (no fish)
Mottled Darner (Aeshna clepsydra) Boggy/marshy edges of lakes
Zigzag Darner (Aeshna sitchensis) Boggy ponds, small bog pools, fen puddles
Subarctic Darner (Aeshna subarctica) Bog ponds, fens, swamps
Green-striped Darner (Aeshna verticalis) Marshy ponds and lakes, slow streams
Spatterdock Darner (Aeshna mutata) Vegetated ponds
Swamp Darner (Epiaeschna heros) Hardwood swamps
Harlequin Darner (Gomphaeschna furcillata) Bogs, boggy swamps, alder and cedar swamps
Cyrano Darner (Nasiaeschna pentacantha) Vegetated ponds
Petite Emerald (Dorocordulia lepida) Boggy ponds and lakes, marshes, cedar swamp streams
Ski-tailed Emerald (Somatochlora elongata) Marshy ponds, small shaded streams, beaver pond outlets
Forcipate Emerald (Somatochlora forcipata) Boggy rills, bogs, and small forested streams
Delicate Emerald (Somatochlora franklini) Bog pools, sping-fed bogs and pools
Kennedy's Emerald (Somatochlora kennedyi) Boggy streams; bogs, fens, and swamps often with flowing water.
Ebony Boghaunter (Williamsonia fletcheri) Boggy pools, forested fens
Painted skimmer (Libellula semifasciata) Marshy forested ponds, vernal pools, slow streams and bogs
Black Meadowhawk (Sympetrum danae) Marshy ponds, bogs, fens

**Distribution Summary:**

County distributions for bog/fen/swamp/marshy pond odonates:

- Southern Spreadwing (Lestes disjunctus australis) ?
- Subarctic Bluest (Coenagrion interrogatum) Essex
- Citrine Fork tail (Ischnura hastata) Windham
- Comet darner (Anax longipes) Windsor
- Mottled Darner (Aeshna claspidea) Rutland
- Zigzag Darner (Aeshna sitchensis) Essex
- Subarctic Darner (Aeshna subarctica) Essex
- Spatterdock Darner (Aeshna mutata) Windham
- Swamp Darner (Epiadeschna heros) Grand Isle
- Harlequin Darner (Gomphaeschna furcillata) Rutland, Lamoille, Orleans, Essex
- Cyrano Darner (Nasiaeschna pentacantha) Windham
- Petite Emerald (Dorocordulia lepida) Caledonia, Essex
- Ski-tailed Emerald (Somatochlora elongata) Bennington, Washington, Caledonia, Essex
- Forcipate Emerald (Somatochlora forcipata) Rutland, Essex
- Delicate Emerald (Somatochlora franklini) Caledonia, Essex
- Kennedy's Emerald (Somatochlora kennedyi) Essex
- Ebony Boghaunter (Williamsonia fletcheri) Washington
- Painted skimmer (Libellula semilasciata) Windsor
- Black Meadowhawk (Sympetrum danae) Washington, Essex

### Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge ✓
- Extensive Local Knowledge □
- Regional Literature ✓
- General Literature ✓

This group consists of several species, the habitat requirements of which vary within the general wetland category. Most species have not been assigned state status ranks, due to incomplete distribution and abundance information, but records for each are very limited. Habitats given for each species refer primarily to reproduction and nymphal requirements; adults of many species require various nearby terrestrial habitats as well. Some dragonflies are known to exhibit "hilltopping" behavior, in which they congregate on tops of hills,
which may be fairly distant from egg-laying sites. This would increase the home range requirements for such species.

Southern Spreadwing (Lestes disjunctus australis) Still water habitats (ponds, swamps, backwaters, bogs, vernal pools)
Subarctic Bluet (Coenagrion interrogatum) Boggy sloughs
Citrine Forktail (Ischnura hastata) Marshy ponds, vernal pools, stream backwaters, seeps
Comet darner (Anax longipes) Vernal pools and semi-permanent ponds (no fish)
Mottled Darner (Aeshna clepsydra) Boggy/marshy edges of lakes
Zigzag Darner (Aeshna sitchensis) Boggy ponds, small bog pools, fen puddles
Subarctic Darner (Aeshna subarctica) Bog ponds, fens, swamps
Green-striped Darner (Aeshna verticalis) Marshy ponds and lakes, slow streams
Spatterdock Darner (Aeshna mutata) Vegetated ponds
Swamp Darner (Epiaeschna heros) Hardwood swamps
Harlequin Darner (Gomphaeschna furcillata) Bogs, boggy swamps, alder and cedar swamps
Cyrano Darner (Nasiaeschna pentacantha) Vegetated ponds
Petite Emerald (Dorocordulia lepida) Boggy ponds and lakes, marshes, cedar swamp streams
Ski-tailed Emerald (Somatochlora elongata) Marshy ponds, small shaded streams, beaver pond outlets
Forcipate Emerald (Somatochlora forcipata) Boggy rills, bogs, and small forested streams
Delicate Emerald (Somatochlora franklini) Bog pools, spring-fed bogs and pools
Kennedy's Emerald (Somatochlora kennedyi) Boggy streams; bogs, fens, and swamps often with flowing water
Ebony Boghaunter (Williamsonia fletcheri) Boggy pools, forested fens
Painted skimmer (Libellula semifasciata) Marshy forested ponds, vernal pools, slow streams and bogs
Black Meadowhawk (Sympetrum danae) Marshy ponds, bogs, fens

Vermont Department of Fish and Wildlife
Comprehensive Wildlife Conservation Strategy
Species Assessment Report

Species Group: Bog/fen/swamp/marshy pond Odonates Group
Scientific Name: *Bog/fen/swamp/marshy pond Odonates Group*

**Description of habitat problem(s):** Many of these wetlands are small, fragile, and could be easily degraded by disturbances within their watershed or groundwater source (e.g., development, clearcutting, hydrologic alterations). There is little specific information available citing negative impacts on these odonates. Several or all of these species utilize a combination of wetland and upland habitat to complete their life cycle; fragmentation of this complex could potentially have a negative effect on these odonates.

**Non-Habitat Problems:**

Unknown Non-Habitat Threats

**Description of non-habitat problem(s):**

**Research and Monitoring Needs**

**Assessment Narrative:**

Little is known about the distribution, abundance, and status of the many rare species in this group. There is existing information which needs to be gathered and compiled. These beetles vary in their distribution and habitat requirements.

Species included:
- Sphaeroderus nitidicollis brevoorti S2 G?T?
- Agonum crenistriatum S2 G?
- Agonum darlingtoni S2 G?
- Agonum decorum S3 G?
- Agonum moerens S3? G?
- Agonum picicornoides S3 G?
- Agonum punctiforme S2? G?
- Agonum superioris S3? G?
- Scaphinotus bilobus S2 G?
- Pterostichus brevicornis S3 G?
- Pterostichus castor S3 G?
- Pterostichus lachrymosus S3 G?
- Pterostichus pinguedineus S2 G?
- Pterostichus punctatissimus S3 G?
- Nebria suturalis S1 G?
- Notiophilus nemoralis S3 G?
- Bembidion rufotinctum S2 G?
- Bembidion cordatum S1 G?
- Bembidion grapei S2 G?
- Bembidion muscicola S3 G?
- Bembidion mutatum S2 G?
- Bembidion quadratulum S2 G?
- Bembidion robusticole S1? G?
- Bembidion rolandi S2 G?
- Bembidion affine S3 G?
- Acupalpus alternans S1? G?
- Acupalpus rectangulus S2? G?
- Diplocheila impressicollis S3 G?
- Diplocheila striatopunctata S3 G?
- Diplocheila assimilis S3 G?
- Pseudamara arenaria S3 G?
- Dyschirius brevispinus S2 G?
- Dyschirius erythrocerus S2 G?
- Dyschirius politus S2 G?
- Elaphropus dolosus S2 G?
- Elaphropus levipes S2 G?

This group contains a great number of species that are ranked as rare, but for which more information is needed before conservation strategies can be developed. Compilation of existing information as well as gathering new data is required.

**Distribution:**

**Natural History Elements:**

- **Home Range:** No
  - Migrant? No
  - Within watershed: No
  - Within biophysical region: No
  - Within VT: No
  - Within Region: No
  - Within US: No
  - Outside US: No

**Distribution Summary:**

Information is needed to determine the probable extent of distribution of these species. Existing collection records and habitat information needs to be reviewed to assess the status of our current knowledge of these species.

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Existing information needs review and new information must be collected to determine the habitat use and requirements of these beetles. Some are known to use specialized habitats and natural communities.

**General Habitat Preferences:**

- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements:
  - Prefers large wetland complexes: No
  - Prefers large expanses of grassland habitat: No
  - Prefers habitat mosaics: No
  - Prefers developed landscapes: No
  - Prefers actively managed woodland: No
  - Requires movement corridors: No
  - Prefers large expanses of forest habitat: No

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Climate Change
Species Group: Carabid Beetles Group
Common Name: Carabid Beetles Group
Scientific Name: Carabid Beetles Group
Species Group: Invert

Conversion of Habitat
Habitat Alteration
Habitat Fragmentation
Unknown Habitat Threats

**Description of habitat problem(s):** Habitat problems are not known for specific species, but would be most related to habitat loss and degradation. Being rare species, habitat fragmentation would lead to smaller, more vulnerable populations.

**Non-Habitat Problems:**

Genetics
Trampling or Direct Impacts
Unknown Non-Habitat Threats

**Description of non-habitat problem(s):** The problems not related to habitat are not known for these beetle and need study. As rare species with often small populations, loss of metapopulation structure and function would be a problem. Some species are alpine, where heavy recreational use can result in trampling.

- **Global Trend:** Unknown  
- **State Rank:**  
- **State Trend:** Unknown  
- **Exterminated in VT?** No  
- **Regionally Rare?** Yes

**Assessment Narrative:**

Three species are included in this group. The cave amphipod is listed as endangered in Vermont. The other amphipod is known only from lakes Champlain and Memphremagog, where it is rarely recorded. The crayfish is found in small coldwater streams and is rare.

An amphipod (Diporeia hoyi) This deepwater species is rarely collected. It has been reported from Lake Champlain and Lake Memphremagog. It may occur in other deep lakes also. This species is cited as being very sensitive to pollution.

Taconic Cave amphipod (Stygobromus borealis) This state-endangered species is known from only a single cave in Vermont. The status of this population is not known. The cave is owned by a conservation organization, but limiting factors to this vulnerable population still exist.

Appalachian Mountain crayfish (Cambarus bartonii) This rare crayfish is only found in small cold water streams and is limited by introduction of the rusty crayfish (Orconectes rusticus) and by development (stormwater sedimentation, acid rain)

**Distribution:**

**Biophysical Regions in Vermont**

- **Champlain Valley:** Certain
- **Northern Green Mtns:** Certain
- **Northern VT Piedmont:** Certain
- **Taconic Mtns:** Certain
- **Vermont Valley:** Certain

- **Home Range:** No
- **Migrant?** No
- **Within watershed**
- **Within biophysical region**
- **Within VT**
- **Within Region**
- **Within US**
- **Outside US**

**Distribution Summary:**

An amphipod (Diporeia hoyi) This species is known in Vermont only from (1) deep water in Lake Champlain from Crown Pt. to Rouses Pt., including Inner Mallets Bay and Missisquoi Bay; and (2) possibly Lake Memphremagog. It may also occur in other large lakes with similar deep water habitat. It was very rare in Lake Champlain 1992-1996 samples.

Taconic Cave amphipod (Stygobromus borealis) This amphipod is known in Vermont only from Dorset (Aeolus) Cave in Dorset. It has also been reported from MA, and NY. It appears to be limited to subterranean drainage systems of karst terrain in the Taconic Mountains. Three single locations comprise the entire global distribution known for this species.

Appalachian Mountain crayfish (Cambarus bartonii) This crayfish is known from the Hudson drainage (Battenkill) and the Champlain Basin. It occurs both in the mountains and in small,
Vermont Department of Fish and Wildlife
Comprehensive Wildlife Conservation Strategy
Species Assessment Report

Common Name: Crustaceans Group
Scientific Name: Crustaceans Group
Species Group: Invert

valley streams.

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

An amphipod (Diporeia hoyi) This is a deepwater species of large lakes, where is undergoes vertical migrations. It has been collected as deep as 900 feet in Lake Superior. It requires cold, deep water with a good oxygen supply. It is likely to be one of the first species to disappear when a lake is polluted.

Taconic Cave amphipod (Stygobromus borealis) In Vermont, this amphipod is found in a cave of marble bedrock with a deep (probably > 9 meters) pool of water with a silt and/or sand bottom. In MA, it was reported from a springhouse.

Applacian Mountain crayfish (Cambarus bartonii) This rare crayfish is only found in small cold water streams.

**General Habitat Preferences:**

- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements:
  - Prefers large wetland complexes: 
  - Prefers large expanses of grassland habitat: 
  - Prefers habitat mosaics: 
  - Prefers developed landscapes: 
  - Prefers actively managed woodland: 
  - Requires movement corridors: 
  - Prefers large expanses of forest habitat: 

**Vegetation Categories Used:**

- Aquatic: Fluvial
- Aquatic: Lacustrine
- Aquatic: Lake Champlain
- Subterranean

(see Appendix B for habitat, community & landscape organization and conservation summaries)

**Current Problems:**

- Habitat Alteration
- Invasion by Exotic Species
- Sedimentation

**Description of habitat problem(s):** D. hoyi is very pollution sensitive, needing clean, cold, well-oxygenated water. It is limited by shifts in food web dynamics caused by zebra mussels. The invasive quagga mussel is displacing D. hoyi in the Great Lakes and could cause similar effects if it reaches Lake Champlain. Long-term deposition of silt is likely altering the benthic habitat this amphipod uses.

S. borealis, due to the nature of its habitat, is vulnerable to such problems as pollution, nutrient shifts, and hydrologic alterations.

Cambarus bartonii is limited by introduction of the rusty crayfish (Orconectes rusticus) and by development (stormwater sedimentation, acid rain)

**Non-Habitat Problems:**

- Pollution
- Reproductive Traits
Common Name: **Crustaceans Group**
Scientific Name: **Crustaceans Group**
Species Group: **Invert**

**Trampling or Direct Impacts**

*Description of non-habitat problem(s):* D. hoyi is pollution sensitive. It is limited by shifts in food web dynamics caused by zebra mussel. S. borealis is vulnerable to collection or other direct loss of individuals due to the small size and isolated nature of the population. The reproductive capability of this species is likely much more limited than that of surface-water inhabiting amphipods because of the limited food supply. This makes rebounding from population losses or poor reproductive years difficult.

Appendix A3: Invertebrate SGCN
Common Name: Freshwater Mussels Group
Scientific Name: Freshwater Mussels Group
Species Group: Invert

Conservation Assessment:
Final Assessment: High Priority
Global Rank: 
Global Trend: Declining
State Rank: 
State Trend: Declining
Exirpated in VT? No
Regionally Rare? Yes

Assessment Narrative:
This group includes seven state-endangered and three state-threatened species. One is also federally endangered. Two of the three remaining species are each known from only a single short stretch of river. Freshwater mussels are recognized as one of the most highly endangered taxonomic groups in North America. Of the 297 native species in the U.S., over 70% are considered endangered, threatened, of special concern, or are resumed extinct. Of Vermont's 18 species, over half are listed as threatened or endangered.

Eastern pearlshell (Margaritifera margaritifera) State threatened
Dwarf wedgemussel (Alasmidonta heterodon) State and federal endangered
Brook floater (Alasmidonta varicosa) State threatened. Only one population, occupying only one river stretch.
Alewife floater (Anodonta implicata) Rare. Occupies a single river stretch.
Cylindrical papershell (Anodontaoides ferussacianus) State endangered
Pocketbook (Lampsilis ovata) State endangered
Fluted-shell (Lasmigona costata) State endangered
Creek heelsplitter (Lasmigona compressa) Rare
Fragile papershell (Leptodea fragilis) State endangered
Black sandshell (Ligumia recta) State endangered. Probably most endangered Vermont mussel.
Pink heelsplitter (Potamilus alatus) State endangered
Giant floater (Pyganodon grandis) State threatened

Distribution:

Natural History Elements:
Home Range: 
Migrant? No
Within watershed
Within biophysical region
Within VT
Within Region
Within US
Outside US

Distribution Summary:
Eastern pearlshell (Margaritifera margaritifera) Reported from the upper Winooski River and Lewis Creek systems of the Champlain basin, and the Passumpsic River, West River, and Nulhegan River systems of the Connecticut River basin.
Dwarf wedgemussel (Alasmidonta heterodon) Connecticut River mainstem, and slightly upstream into some large tributaries. Historically found from Bloomfield to Brattleboro. More recently known from Hartland to Springfield, and from Guildhall to
**Common Name:** Freshwater Mussels Group  
**Scientific Name:** Freshwater Mussels Group  
**Species Group:** Invert

Lunenburg.
Brook floater (Alasmidonta varicosa) Known only from West River (Connecticut River tributary). One historic report from the Connecticut River mainstem at Norwich.

Elktoe (Alasmidonta marginata) Known only from a short stretch (~ 5 miles) of the Lamoille River in Fairfax and Georgia.

Alewife floater (Anodonta implicata) Occurs in Connecticut River from Bellows Falls to Massachusetts.

Cylindrical papershell (Anodontoides ferussacianus) Known from Missisquoi, Lamoille, and Poultnay river systems, and also Stone Bridge Brook (Milton). May occur in other Lake Champlain rivers and the main lake itself. One historic report from the Clyde River.

Pocketbook (Lampsilis ovata) Champlain basin species: reported from Lake Champlain, Missisquoi River, Lamoille River, Winooski River, LaPlatte River, Lewis Creek, Otter Creek, and Poultnay River. Only found below principal fall line.

Fluted-shell (Lasmigona costata) Champlain basin species: reported from Lamoille River, Winooski River, Otter Creek, Lewis Creek, and Poultnay River. Shells have been taken in the Missisquoi River, but no live specimens have been observed. Observed above the principal fall line only in Otter Creek.

Creek heelsplitter (Lasmigona compressa) Reported from several small to large tributaries to Lake Champlain. Primarily a headwater to medium-sized creek species, but does occur in larger habitats (e.g., below fall line in Winooski River). One record is from outside the Champlain basin, the Coaticook River (Norton).

Fragile papershell (Leptodea fragilis) Lake Champlain basin only; reported from Lake Champlain, Missisquoi River, Lamoille River, Winooski River, Otter Creek, and Poultnay River. Only found below principal fall line.

Black sandshell (Ligumia recta) Champlain basin species; reported from Missisquoi River, Otter Creek, Poultnay River, and Hospital Creek, and shallow areas in Lake Champlain near the mouths of these rivers. Appears extirpated from Hospital Creek; most recent survey did not find it in Otter Creek. Only found below principal fall line.

Pink heelsplitter (Potamilus alatus) Champlain basin species; reported from Lake Champlain, Missisquoi River, Lamoille River, Winooski River, Otter Creek, Lewis Creek, Hospital Creek, and Poultnay River. Only found below principal fall line.

Giant floater (Pyganodon grandis) Champlain basin species; reported in Lake Champlain, Missisquoi River, Lamoille River, Winooski River, Otter Creek, East Creek, and Poultnay River. Reported from above the principal fall line only in Otter Creek and Lamoille River.

<thead>
<tr>
<th>Species</th>
<th>Habitat Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Eastern pearlshell (Margaritifera margaritifera)</td>
<td>This is a coldwater species, found in streams that support trout populations. It inhabits firm sand substrates, often amidst gravel and cobbles, and occasionally tightly packed cobbles and gravel. Salmonids are the fish hosts.</td>
</tr>
<tr>
<td>Dwarf wedgemussel (Alasmidonta heterodon)</td>
<td>A large river species, this mussel is found in stable mud, silty sand, sand, or gravel where the current is sufficient to keep the substrate free of surficial silt. Fish hosts may include the tessellated darter and slimy sculpin.</td>
</tr>
<tr>
<td>Elktoe (Alasmidonta marginata)</td>
<td>This is a mussel of medium-sized rivers, where it occupies riffles or rapids on stable gravel or rocky bottoms. It burrows securely into the sand-filled spaces between stones.</td>
</tr>
<tr>
<td>Brook floater (Alasmidonta varicosa)</td>
<td>This mussel occupies small rivers, where it is found in rocky or gravel substrates and in sandy shoals. It is usually found in or adjacent to rapids or riffles. Mussel beds usually support some submerged aquatic plants.</td>
</tr>
<tr>
<td>Pocketbook (Lampsilis ovata)</td>
<td>This mobile mussel is found primarily in stretches of larger rivers from Lake Champlain to the first major waterfall. It also can be found in shallow areas of the main lake near deltas of these rivers. Mussels occupy firmly packed sand, sand and gravel, or silty sand.</td>
</tr>
<tr>
<td>Fluted-shell (Lasmigona costata)</td>
<td>This mussel is found primarily in medium-sized creeks to larger rivers from Lake Champlain to the first major waterfall, but also occurs above this fall line in some streams. It inhabits a variety of substrates, including mud, sand, gravel, and aggregates of cobble, gravel, and sand.</td>
</tr>
<tr>
<td>Creek heelsplitter (Lasmigona compressa)</td>
<td>This is a mussel of small creeks to small rivers, but occurs in small numbers in large river sections above Lake Champlain as well. It if found in gravel, sand, or mud.</td>
</tr>
<tr>
<td>Pink heelsplitter (Potamilus alatus)</td>
<td>This mussel occurs in large rivers only between Lake Champlain and the first major waterfall. It also occupies areas of Lake Champlain adjacent to the deltas of these rivers. It is found in clay, clayey silt, sand, gravel and sand, or mixtures of cobble, sand, and silt. Pink heelsplitters usually bury themselves nearly completely into the substrate, their shape anchoring them securely in place.</td>
</tr>
<tr>
<td>Fragile papershell (Leptodea fragilis)</td>
<td>This mussel occurs in large rivers only between Lake Champlain and the first major waterfall. It also occupies areas of Lake Champlain adjacent to the deltas of these rivers. It is found in sand, clayey silt, silty sand, or gravel and sand. Fragile papershells usually bury themselves nearly completely into the substrate, their shape anchoring them securely in place.</td>
</tr>

- **Species Group:** Invert

Major waterfall. Substrates include sand, sand and gravel, and mud.

- **Giant floater (Pyganodon grandis):** A mobile species of large rivers and lakes, it is found in sand, sand and gravel, silty sand, and clay.

- **Cylindrical papershell (Anodontaferussacianus):** These mussels are found in creeks and rivers, but likely occupy shallow lake habitat as well (Lake Champlain). Substrates include silt and silty sand in slow currents. It is found primarily below the first waterfall upstream of Lake Champlain, but is known from well above this barrier in the Lamoille River.

- **Alewife floater (Anodonta implicata):** This is a riverine mussel in Vermont found in slow to fast waters. It occurs in a variety of substrates, including sand, sand and gravel, and silt.

**Potential Fish hosts reported:**
- Eastern pearlshell: Rainbow trout, Atlantic salmon, brook trout
- Dwarf wedgemussel: tessellated darter, slimy sculpin
- Elk toe white sucker, rock bass
- Brook floater: slimy sculpin, longnose dace, blacknose dace, golden shiner, pumpkinseed, yellow perch, tessellated darter
- Pocketbook smallmouth bass, white crappie, largemouth bass, bluegill, sauger, yellow perch
- Fluted-shell carp, spotfin shiner, longnose dace, slimy sculpin, black crappie, yellow perch
- Creek heelsplitter: slimy sculpin, black crappie, spotfin shiner, yellow perch
- Pink heelsplitter: freshwater drum
- Fragile papershell: freshwater drum
- Black sandshell: banded killifish, bluegill, redbreast sunfish, rock bass, white perch, white crappie, largemouth bass, sauger, yellow perch, walleye
- Giant floater: banded killifish, blackchin shiner, black crappie, blacknose dace, bluegill, bluntnose minnow, brook silverside, carp, brook stickleback, common shiner, creek chub, freshwater drum, gizzard shad, golden shiner, largemouth bass, longnose gar, pearl dace, pumpkinseed, rock bass, white crappie, white sucker, yellow bullhead, yellow perch
- Cylindrical papershell: spotfin shiner, black crappie; possibly sea lamprey and mottled sculpin
- Alewife floater: American shad, alewife

*Primarily from lab studies; this list does not indicate that fish hosts have been demonstrated in natural environment.

**Appendix A3: Invertebrate SGCN**

*Vermont’s CWCS 9/7/2005* 15
**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Invasion by Exotic Species
- Sedimentation

_Habitat Problem_:
- Zebra mussels are decimating Lake Champlain mussel populations, and are being found in the lower portions of some of the lake's tributaries.
- Bridge construction and road-related river bank stabilization have been common direct impacts.
- Dams have been responsible for large losses of habitat, particularly in the Connecticut River. Dams have also altered and degraded downstream habitats.

**Non-Habitat Problems:**
- Genetics
- Harvest or Collection
- Pollution
- Predation or Herbivory
- Reproductive Traits
- Trampling or Direct Impacts

_Non-Habitat Problem_:
- Loss of specific fish hosts can result in reduced/eliminated reproductive success.
- Muskrats are mussel predators and can decimate local populations when their numbers are too high or when a mussel species is particularly vulnerable.
- Black sandshell populations are extremely limited in number of individuals and age. Females are rarely found, if ever; juveniles are never found in Vermont. The low densities and skewed sex ratio are undoubtedly hampering reproductive success and may have genetic consequences.
- Mussels have been shown to be sensitive to a variety of pesticides and other anthropogenic chemicals. Use of mussels as bait by anglers has been problematic in some other states. This has not been investigated in Vermont.
- Damage to/death of mussels due to trampling by stream users may occur regularly, but has not been investigated. Thin-shelled species are often found dead due to breakage.
- Walleye sampling using large seines has resulted in large numbers (1000's) of mussels being dragged ashore at Sandy Point in Swanton in the past. These included some listed species. Many can be returned to the water, but some (particularly giant floaters) are fatally damaged.
**Common Name:** Freshwater Mussels Group

<tr>
<td>Research</td>
<td>Basic Life History</td>
<td>High</td>
<td>Determine host fish requirements for each mussel species. This needs to be specific to Vermont populations.</td>
</tr>
<tr>
<td>Research</td>
<td>Distribution and Abundance</td>
<td>High</td>
<td>1) Obtain baseline information on distribution and abundance of each mussel species. This should include all existing information sources. 2) Conduct inventories of rivers and appropriate lake habitat to detect and gather information on new SGCN mussel populations.</td>
</tr>
<tr>
<td>Research</td>
<td>Threats and Their Significance</td>
<td>High</td>
<td>Assess limiting factors and their potential impacts to the aquatic habitats of each mussel species. Assessment should be on a watershed scale, including upland sources of potential limiting factor. Research is needed on how to protect native mussel populations that are being impacted by zebra mussels, and also those populations that are vulnerable to further zebra mussel colonization.</td>
</tr>
<tr>
<td>Research</td>
<td>Population Genetics</td>
<td>Medium</td>
<td>1) Certain species (e.g., black sandshell, elktoe) are highly isolated from nearest populations. Genetic comparisons with other populations will be needed before reintroduction options can be evaluated. 2) Determine genetic constraints that may be hampering the recovery of isolated SGCN mussel populations (particularly black sandshell and elktoe).</td>
</tr>
<tr>
<td>Research</td>
<td>Taxonomy</td>
<td>Medium</td>
<td>There is uncertainty about the species assignment of Lampsilis ovata. Vermont populations may be L. cardium, or more than one species could be here. This needs to be determined.</td>
</tr>
<tr>
<td>Research</td>
<td>Other Research</td>
<td>High</td>
<td>Investigate the potential benefits of dam removal to SGCN mussel populations</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Population Change</td>
<td>Medium</td>
<td>Monitor known SGCN mussel populations. Population monitoring could be employed to track population trends at distinct locations. This would follow field surveys and assessments to identify populations judged to be large and viable. Focusing on such large populations would offer greater probability of detecting population shifts. Areas of habitat where species have disappeared need to be tracked.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Monitor Threats</td>
<td>High</td>
<td>Zebra mussel monitoring is needed in watersheds that support these native species. Occupied rivers and boating lakes that occur upstream need to be monitored. The effects of dams on downstream habitat needs to be monitored, including de-watering, temperature regime, and silt releases.</td>
</tr>

### Conservation Assessment:

**Final Assessment:** High Priority  
**Global Rank:**  
**Global Trend:** Declining  
**Extirpated in VT?** Yes  
**Regionally Rare?** Yes

**Assessment Narrative:**

A diverse group of snails whose general status ranges from extirpated to declining to rare. Much work is needed to refine status assessment.

- **Fingered valvata (Valvata lewisi)**: Two locales recorded: a lake, a vernal pool. Possibly occurs elsewhere. Only found in low numbers throughout range.
- **Mossy valvata (Valvata sincera)**: Three records only; Lake Champlain valley only.
- **Squat duskysnail (Amnicola (Lyogyrus) grana)**: Four records, scattered in Vermont. An East Coast species.
- **Canadian duskysnail (Amnicola (Lyogyrus) walkeri)**: One site known.
- **Buffalo pebblesnail (Gillia altilis)**: Fourteen records known, most in Champlain valley. Atlantic drainage species.
- **Pupa duskysnail (Lyogyrus (Amnicola) pupoidea)**: Six records, all Lake Champlain. Hybridization with A. grana reported.
- **Boreal marstonia (Marstonia (Pyrgulopsis) decepta)**: Only known from Lake Champlain, where uncommon to rare. Uncommon in northern part of range; more common southward. Reported as abundant at some Massachusetts sites.
- **Liver elimia (Goniobasis livescens)**: Known only from northern Lake Champlain (9 sites). May become extirpated due to the exotic Bithnia tinticulata (snail). Still "uncommon" at this point, as opposed to "rare".
- **Sharp hornsnail (Pleurocera acuta)**: Reported from Vermont in literature, but there are no occurrence records at DEC.
- **Spindle lymnaea (Acella haldemani)**: Two locations known; limited and localized in distribution. Appears to be greatly reduced from historical range. Often only one location is reported for a lake, but it is easily overlooked. Rare. Reproduction may be a limiting factor.
- **Mammoth lymnaea (Bulimnea megastoma)**: Reported from Lake Champlain and its tributaries in 19th century literature; only a few sites were reported though. Was never abundant. May have been extirpated from NY by 1971. The species is probably extirpated in Vermont as well. DEC has no records of occurrence.
- **Country fossaria (Fossaria rusticola)**: Two sites known, both in Champlain valley. There may be some taxonomic issues with genus and species (e.g., it may be subspecies/variety of F. modicella).
- **Disco gyro (Gyraulus circumstriatus)**: Found recently in several vernal pools, also in some wetlands.
- **Star gyro (Gyraulus crista)**: Only known from 5 sites in Vermont. Holarctic (northern) distribution. Rare in NY.
Common Name: Freshwater Snails Group
Scientific Name: Freshwater Snails Group
Species Group: Invert

Distribution:

Natural History Elements:

Home Range:
Migrant? No
Within watershed □
Within biophysical region □
Within VT □
Within Region □
Within US □
Outside US □

Distribution Summary:

Mossy valvata (Valvata sincera) Three records only; Lake Champlain only, including Dead Creek. St. Lawrence system only in NY (4 pops.)

Squat duskysnail (Amnicola (Lyogyrus) grana) Four records: Connecticut River, Lake Fairlee, and Lake St. Catherine. An East Coast species.

Canadian duskysnail (Amnicola (Lyogyrus) walkeri) Lake St. Catherine is only known site.

Buffalo pebblesnail (Gillia altilis) Fourteen records known, most in Champlain valley: Lake Champlain, Lamoille River, Missisquoi River. Connecticut River, Hinkum Pond (Sudbury), and Poultney River. Atlantic drainage species.

Pupa duskysnail (Lyogyrus (Amnicola) pupoidea) Six records, all Lake Champlain.

Boreal marstonia (Marstonia (Pyrgulopsis) decepta) Only known from Lake Champlain.

Liver elimia (Goniobasis livescens) Known only from northern Lake Champlain (9 sites). Found in many NY waterbodies.

Sharp hornsnail (Pleurocera acuta) Reported from Vermont in literature ("QE, VT, and northeastern NY"), but there are no occurrence records at DEC.

Spindle lymnaea (Acella haldemani) Two locations known: Beebe Pond and Otter Creek. Limited and localized in distribution. Historically in Lake Champlain, but there are no recent records from there. Appears to be greatly reduced from historical range. Often only one location is reported for a lake, but it is easily overlooked. Rare and sporadic in occurrence rangewide.

Mammoth lymnaea (Bulimnea megastoma) Reported from Lake Champlain and its tributaries in 19th century literature; only a few sites were reported though. Was never abundant. May have been
**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

**Fingered valvata** (Valvata lewisi) A pool/pond/lake species. Found particularly on sand, but also mud and aquatic vegetation down to 7 m.

**Mossy valvata** (Valvata sincera) Generally limited to oligotrophic and mesotrophic situations, but occasionally in eutrophic waters. Associated with submerged aquatic vegetation. In MA, however, it is reported as requiring deep lakes with a pH of 7.6 or greater, where it is often associated with rooted vegetation.

**Squat duskysnail** (Amnicola (Lyogyrus) grana) Found on organic debris and vegetation in standing waters of larger lakes and ponds, oxbows, and major rivers. Highly tolerant of acidic conditions, but limited tolerance to sodium (e.g., road salt).

**Canadian duskysnail** (Amnicola (Lyogyrus) walkeri) Found in sluggish streams and quiet ponds where dead plants accumulate. Occupies lentic waters, ranging from oligotrophic to marl ponds.

**Buffalo pebblesnail** (Gillia altilis) Large lakes and rivers. In Hudson River, it is found on mud and aquatic plants in the shallows.

**Pupa duskysnail** (Lyogyrus (Amnicola) pupoidea) Occurs in small to large ponds and large rivers. Found on organic debris and aquatic plants. Hybridization with A. grana reported.

**Boreal marstonia** (Marstonia (Pyrgulopsis) decepta) Found on stonewort (Chara) on soft and hard marly substrates.

**Liver elimia** (Goniobasis livescens) Grazes in shallow water on stones and gravel in lakes and clear rapid streams. In lakes, it burrows into the sand and feeds on algae and bacteria; this is not as good a food source as it is for other pulmonate snails.

**Sharp hornsnail** (Pleurocera acuta) Found in a variety of habitats. In lakes, found on boulders on exposed shores or in mud and sand. In rivers, found on stones in rapid current. Snails remain in shallow water up to 1 m deep, where they burrow under the sand and layers of decaying leaves and other organic matter.

**Spindle lymnaea** (Acella haldemani) Found on submerged logs, silt, sand, and mud; up to 2 m deep. Often is attached to leaves and stems of aquatic pondweed and other submerged vegetation. Reported to favor eutrophic lakes and ponds. Young don't travel far from where they hatched, leading to a clumped distribution.

**Mammoth lymnaea** (Bulimnea megastoma) Found in ponds, large and small lakes, and quiet embayment of rivers.

**Country fossaria** (Fossaria rustica) Occupies rivers and streams, lakes, ponds, and occasionally ditches and canals. Can be in damp mud flats and bodies of water with fluctuations in water level.

**Disco gyro** (Gyralus circumstriatus) In Vermont, appears to be primarily a vernal pool species, but also found in lake-associated wetlands. Described as being found in quiet waters of lakes and ponds, intermittent streams, and temporary [intermittent] ponds. Found on mud to gravelly sands, often associated with dead and living plants. Intolerant of low pH waters. Also described as a species of temporary waters.
Common Name: **Freshwater Snails Group**  
Scientific Name: **Freshwater Snails Group**  
Species Group: **Invert**

Star gyro (Gyraulus crista) Found in dense aquatic vegetation, water-logged wood, and rotting terrestrial leaves (in water).

**General Habitat Preferences:**

- **Minimum Elevation (m):** 0  
- **Maximum Elevation (m):** 0  
- **Patch Size Requirements:**
  - Prefers large wetland complexes: False  
  - Prefers large expanses of grassland habitat: False  
  - Prefers habitat mosaics: False  
  - Prefers developed landscapes: False  
  - Requires movement corridors: False  
  - Prefers large expanses of forest habitat: False  

**Vegetation Categories Used:**

- Aquatic: Fluvial  
- Aquatic: Lacustrine  
- Aquatic: Large Lake Champlain Tribs Below Falls  
- Aquatic: Lower CT River  
- Floodplain Forests  
- Marshes and Sedge Meadows  
- Seeps and Pools  
- Shrub Swamps  
- Wet Shores  

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Conversion of Habitat  
- Habitat Alteration  
- Habitat Fragmentation  
- Invasion by Exotic Species  
- Sedimentation  

**Description of habitat problem(s):** Acidification (acid rain) is a problem to several species.  
Valvata sincera - lake drawdowns may be a problem to this species.  
Gyraulus circumstriatus - intolerant of low pH waters; acid rain may be a problem.

**Non-Habitat Problems:**

- Pollution  
- Reproductive Traits  

**Description of non-habitat problem(s):** Some lake/pond species are vulnerable to chemical treatment of these waters to control algae, swimmers itch, etc.  
Valvata lewisi - only found in very low densities throughout range; this may limit long-term viability of local populations.  
Valvata sincera - low reproductive rate. Only a few eggs (4-12) produced per individual.  
Amnicola grana - low tolerance to sodium (e.g., road salt). This may impact populations anywhere they are found (particularly in rivers).  
Lyogyrus pupoidea - reported to hybridize with Amnicola grana. This could jeopardize both species where they co-occur.  
Goniobasis livescens - Likely being impacted by the exotic Bithnia tinticulata (snail) in Lake Champlain. Region mollusc expert Dr. Doug Smith (Umass) believes it will become extirpated from the lake for this
Common Name: **Freshwater Snails Group**  
Scientific Name: **Freshwater Snails Group**  
Species Group: **Invert**

Acella haldemani - Apparently greatly reduced in distribution and abundance from historical range for unknown reasons. The young don't travel far from where the hatch, which creates limited ability to disperse and colonize/recolonize other habitat patches. Bulimnea megastoma - may have been extirpated due to unknown causes.

Grassland Butterflies Group

Common Name: Grassland Butterflies Group
Scientific Name: Grassland Butterflies Group
Species Group: Invert

Conservation Assessment:

Final Assessment: High Priority
State Rank: 
Exirpated in VT? Yes

Assessment Narrative:

Regal fritillary is extirpated; other species are extremely rare in Vermont. Persius duskywing has declined drastically in the Northeast, now being limited to a few small, fragmented populations.

This group consists of four species, the habitat requirements of which vary within the general grasslands category. Regal fritillary is extirpated in Vermont and almost all of the Northeast. The other species are very rare in Vermont. Habitats given for each species refer to required host plants.

Cobweb skipper (Hesperia metea) Grasslands, prairies, barrens, and old fields with little bluestem (Andropogon scoparius) and big bluestem (A. gerardi).
Persius duskywing (Erynnis persius) Open areas with lupine
Regal fritillary (Speyeria idalia) Tall-grass prairie and other open sites including damp meadows, marshes, wet fields, and mountain pastures.
Dusted Skipper (Atrytonopsis hianna) Grasslands, prairies, barrens, and old fields with little bluestem (Andropogon scoparius) and big bluestem (A. gerardi).

Species Assessment Report

Common Name: Grassland Butterflies Group
Scientific Name: Grassland Butterflies Group
Species Group: Invert

Habitat Description:
Habitat Information is based on the following:

Limited Local Knowledge☐ Extensive Local Knowledge☐ Regional Literature ☐ General Literature ☐

This group consists of four species, the habitat requirements of which vary within the general grasslands category. Regal fritillary is extirpated in Vermont and all of North America east of the Mississippi River except for one location in central PA. The other species are very rare in Vermont. Habitats given for each species refer to required host plants.

Cobweb skipper (Hesperia metea) Grasslands, prairies, barrens, and old fields with little bluestem and big bluestem
Persius duskywing (Erynnis persius) Open areas with wild lupine
Regal fritillary (Speyeria idalia) Tall-grass prairie and other open sites including damp meadows, marshes, wet fields, and mountain pastures.
Dusted Skipper (Atrytonopsis hianna) Grasslands, prairies, barrens, and old fields with little bluestem (Andropogon scoparius) and big bluestem (A. gerardi).

General Habitat Preferences:
Minimum Elevation (m): 0
Maximum Elevation (m): 0
Patch Size Requirements:
Prefers large wetland complexes: ☐
Prefers large expanses of grassland habitat: ☑
Prefers habitat mosaics: ☐
Prefers developed landscapes: ☐
Prefers actively managed woodland: ☐
Requires movement corridors: ☐
Prefers large expanses of forest habitat: ☐

Vegetation Categories Used:
(see Appendix B for habitat, community & landscape organization and conservation summaries)
Grasslands and Hedgerows
Oak-Pine Northern Hardwood

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
Conversion of Habitat
Habitat Alteration
Habitat Fragmentation
Habitat Succession
Impacts of Roads or Trails
Inadequate Disturbance Regime

Description of habitat problem(s): Persius duskywing is extremely rare and requires wild lupine as larval food plant. It is therefore unlikely to be well established in Vermont unless this plant is reintroduced and the habitat managed for these species, or if an alternate larval food plant is discovered.

Non-Habitat Problems:
Common Name: Grassland Butterflies Group  
Scientific Name: Grassland Butterflies Group  
Species Group: Invert

Loss of Relationship with Other Species  
Trampling or Direct Impacts

Description of non-habitat problem(s):

**Assessment Narrative:**

Individual species in this group are rare in Vermont; several are regionally or globally rare.

This group consists of several species, the habitat requirements of which vary within the general hardwood forest category. Most species have not been assigned state status ranks, due to incomplete distribution and abundance information, but records for each are very limited. Caterpillars depend on specific food plants, which are often themselves rare (e.g., hackberry, scrub oak).

- West Virginia white (Pieris virginiensis) - Rich hardwood forest with toothwort (larval host plant)
- Early hairstreak (Erora laeta) - American beech stands (larval host plant; feeds on nuts and leaves)
- Hackberry emporer (Asterocampa celtis) - Floodplain forest with hackberry stands (larval host plant)
- Tawny emporer (Asterocampa clyton) - Floodplain forest with hackberry stands (larval host plant)
- Edwards' hairstreak (Satyrium edwardsii) - Sand plain woodland/ pitch pine-oak-heath rocky hill and other similar habitat that contain either scrub or black oak stands (larval host plants)

**Distribution:**

**Natural History Elements:**

- Home Range: No
- Migrant? No
- Within watershed
- Within biophysical region
- Within VT
- Within Region
- Within US
- Outside US

**Distribution Summary:**

Town records:
- Hackberry emperor - Burlington, Salisbury, Windsor
- Tawny emporer Colchester, Orange, Richmond
- Edwards' hairstreak - Pownal
Common Name: Hardwood Forest Butterflies Group  
Scientific Name: Hardwood Forest Butterflies Group  
Species Group: Invert

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

This group consists of several species, the habitat requirements of which vary within the general hardwood forest category. Most species have not been assigned state status ranks, due to incomplete distribution and abundance information, but records for each are very limited. Caterpillars require specific food plants, which are often themselves rare (e.g., hackberry, scrub oak).

- West Virginia white (Pieris virginiensis) rich hardwood forest with toothwort (larval host plant)
- Early hairstreak (Erora laeta) American beech stands (larval host plant)

**General Habitat Preferences:**

- **Minimum Elevation (m):** 0
- **Maximum Elevation (m):** 0
- **Patch Size Requirements:**
  - Prefers large wetland complexes:
  - Prefers large expanses of grassland habitat:
  - Prefers habitat mosaics:
  - Prefers developed landscapes:
  - Requires movement corridors:
  - Prefers large expanses of forest habitat:

**Vegetation Categories Used:**

- Floodplain Forests
- Northern Hardwood
- Oak-Pine Northern Hardwood

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Invasion by Exotic Species

*Description of habitat problem(s):* Early hairstreak is limited by the loss of American beech stands due to beech bark disease. Caterpillars feed on the fruits of this tree, which are only produced by individuals 40 years old or more. Invasion of garlic mustard may limit the West Virginia White, as the adults will lay eggs on it. The plant is reported to be toxic to eggs/larvae.

**Non-Habitat Problems:**
- Genetics
- Loss of Relationship with Other Species
**Common Name:** Hardwood Forest Butterflies Group  
**Scientific Name:** Hardwood Forest Butterflies Group  
**Species Group:** Invert

**Description of non-habitat problem(s):** Asterocampa populations are far from closest known sites; these are not vagile species.

**Assessment Narrative:**

Individual species in this group are rare in Vermont; several are regionally or globally rare.

This group consists of several species, the habitat requirements of which vary within the general lakes/ponds category. Most species have not been assigned state status ranks, due to incomplete distribution and abundance information, but records for each are very limited. Habitats given for each species refer primarily to reproduction and nymphal requirements; adults of many species depend on various nearby terrestrial habitats as well. Some dragonflies are known to exhibit “hilltopping” behavior, in which they congregate on tops of hills, which may be fairly distant from egg-laying sites. This would increase the home range requirements for such species. Taxonomic uncertainty of Enallagma cyathigerum/E. vernale populations warrants investigation.

New England Bluet (Enallagma laterale)  Vegetated ponds  
Vernal Bluet (Enallagma vernale)  Lakes, rivers, marshy ponds and lakes  
Slender Bluet (Enallagma traviatum)  Lakes and ponds with vegetation  
Lilypad Forktail (Ischnura kellicotti)  Ponds with lilypads  
Ringed Emerald (Somatochlora albicincta)  Cold ponds  
Lake Emerald (Somatochlora cingulata)  Shallow cold lakes, sluggish rivers and streams  
White Corporal (Libellula exusta)  Muck-bottomed lakes and ponds, slow streams; bog-bordered lakes and ponds

**Distribution:**

**Common Name:** A slave-making ant  
**Scientific Name:** Leptothorax n. sp.  
**Species Group:** Invert

### Conservation Assessment:

**Final Assessment:** High Priority  
**Global Rank:**  
**Global Trend:** Unknown  
**State Rank:**  
**State Trend:** Unknown  
**Exirpated in VT?** Unknown  
**Regionally Rare?** Yes

### Assessment Narrative:

This is apparently a very rare species, only known from two sites globally. The sites are about 20 km apart.

This species is known from only two sites worldwide. At least one of these is in Vermont. This site is in a state park, which could provide some protection; however, the ant is not a conservation target for the park at this time. This species and its habitat are not currently afforded protected. This may be a species endemic to Vermont, depending on the location of the second site. More survey work is needed, however, to determine the extent of its range.

This slave-making ant was first collected at Niquette Bay State Park in 1986, but has not been found since then, despite 14 years of collecting effort at the park subsequent to the initial discovery. Information for the second site has not been pursued.

### Distribution:

  - Yes
- **Outside US**
  - Yes

**Distribution Summary:**

The original site where this species was discovered in Niquette Bay State Park, Colchester. The second and only other reported site is described as being "about 20 km from our VT [NBSP] site."

### Habitat Description:

Habitat Information is based on the following:

- **Limited Local Knowledge**
- **Extensive Local Knowledge**
- **Regional Literature**
- **General Literature**

This species utilizes a social "parasite" strategy, enslaving workers of other ant species to perform tasks of the nest. The slavemakers and their hosts live in preformed plant cavities such as hollow sticks and acorns in the litter and surface soil layers. The Vermont state park site is described in literature as second-growth temperate deciduous forest that has been protected from logging since the 1930's. The forest is dominated by oaks, while hemlock, birch, and pine contribute strongly to the canopy. The site is flat, possibly situated on a floodplain at
Vermont Department of Fish and Wildlife
Comprehensive Wildlife Conservation Strategy
Species Assessment Report

Common Name: A slave-making ant
Scientific Name: Leptothorax n. sp.
Species Group: Invert

about 30m elevation. This slave-making ant lives in complex colonies that can occupy more than one physical location, termed polydomy. A colony represents a family unit and is typically fractionated into several "nests". There is differing information on whether these individual nests regroup in autumn or remain spatially stable. A nest, comprised of a local group of ants cohabiting a particular domicile, may or may not contain the colony's queen. Nests of a colony tend to be spatially clustered. Two host ant species were reported as being used by Leptothorax sp. at the Niquette Bay State Park site. A second and more abundant species of slave-making ant also inhabits this site and utilizes the same host species.

Vegetation Categories Used:

Oak-Pine Northern Hardwood

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation

Description of habitat problem(s): Oaks are necessary, as they supply acorns used for habitation. Loss/reduction of oaks would impact habitat availability.

Non-Habitat Problems:
- Competition
- Loss of Relationship with Other Species
- Pollution
- Unknown Non-Habitat Threatss

Description of non-habitat problem(s): Any herbicide or insecticide use could negatively impact this ground-dwelling species. Abundance has been declining at the state park for many species of ants, including the hosts of Leptothorax sp. This could result in loss of colony functions and could reduce survival. The other slave-making ant known from this site is more abundant and utilizes the same host ant species and habitat. It does not appear to yet be impacted by declining host numbers. There may be significant competition for nesting cavities. Low abundance of Leptothorax sp. makes this ant vulnerable to fluctuations in population density.

Appendix A3: Invertebrate SGCN Vermont's CWCS 9/7/2005 35
Common Name:  A slave-making ant  
Scientific Name:  Lepto thorax n. sp.  
Species Group:  Invert

Recolonization or rebound following large population drops may not be possible.

**Known Watersheds**

Hudson-Hoosic Rivers

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Tomah mayfly (Siphlonisca aerodromia) This mayfly inhabits rivers with broad, seasonally flooded sedge-dominated floodplains.

Roaring Brook mayfly (Epeorus frisoni) This species inhabits small creeks. It has been reported from first and second order streams in NY and ME.

Ameletus browni Habitat is unknown for this species.

Eurlophella bicoloroides This is a stream/river species; the specific habitat is unknown.

Baetisca rubescens This is a stream/river species; the specific habitat is unknown.

Alloperla voinae Habitat is unknown for this species.

Rhyacophila brunnea Known from Killington, Shrewsbury, Mendon, Orange, and Stowe.

#### Assessment Narrative:

Numerous species of moths are considered rare, declining, or extirpated. Very little information is available on the distribution of these species, and there is even less known about their trends throughout the region. They are treated here together as a single group due to this dearth of information.

The following species:

- **Sthenopis thule** A ghost moth  Single specimen, South Hero in '92. LFP*: reported on willows, but not well known.
- **Itame ribearia** Currant spanworm  Collected Bakersfield, '91 (Franklin Co). LFP: currant, gooseberry. Formerly widespread, now rare through much of range due to eradication of currant in 1920's-'60's (alternate host of white pine blister rust).
- **Eacles imperialis pini** Imperial moth  One collected Grand Isle, '01; Chittenden Co. historically. White pine specialist; possibly also pitch pine. Found in coniferous forest. Declined drastically or disappeared from VT in '50's. Probable cause of decline was pesticide spraying and release of Compsilura concinnata for gypsy moth control. Use of BTK is also potential limiting factor if used wrong time of year (late June or later). Hemileuca lucina  New England buckmoth  Restricted to New England; found in SE VT. Found in wet meadows and open fields. LFP: oak, Prunus serotina, willows, gray birch, Vaccinium; early instars on meadowsweet.
- **Sphinx drupiferarum** Plum sphinx or Wild cherry spinx  Reported from Franklin, Chittenden, Bennington, Orleans, and Lamoille counties. Populations declining in Eastern NA; uncommon to rare throughout range. Drastically reduced/extirpated over much of range, reportedly due to aerial (DDT) spraying. Found in wooded habitats and suburbs. LFP: cherry, plum, apple; also lilac and hackberry.
- **Sphinx eremitus** Hermit sphinx  Reported from Franklin, Windsor, and Grand Isle counties. Populations declining range-wide. LFP: Monarda, Mentha, Lycopis, Salvia.
- **Sphinx luscitiosa** Clemens' sphinx  Populations declining range-wide. Uncommon or rare throughout Northeast. LFP: willow, poplar, birch, apple, ash.
- **Lasionycta taigata** A noctuid moth  Reported from Essex Co. '75 (Moose Pond). A bog associate.
- **Lemmeria digitalis** A noctuid moth Several collected in Chittenden Co., 1991-93.
- **Xestia fabulosa** A noctuid moth  Range not well-known. Recorded from VT, NH, and ON. (Previously in genus Anomogyna). LFP: Vaccinium sp.
- **Zanclognatha martha** Pine barrens zanclognatha  Reported from Jericho Research Forest (Chittenden Co.) in '90. Somewhat rare outside of NJ. Found in pitch pine/scrub oak barrens in PA northward; Jericho population may have colonized pines from a remnant pine barren.

---

### Vermont's CWCS 9/7/2005

Appendix A3: Invertebrate SGCN
Common Name: **Moths Group**  
Scientific Name: **Moths Group**  
Species Group: Invert

* LFP is larval food plant.

**Distribution:**

**Natural History Elements:**

- **Home Range:**
  - Migrant? No
  - Within watershed
  - Within biophysical region
  - Within VT
  - Within Region
  - Within US
  - Outside US

**Distribution Summary:**

The following species:
- *Sthenopis thule* A ghost moth Single specimen, South Hero in '92.
- *Itame ribearia* Currant spanworm Collected Bakersfield, '91 (Franklin Co). Formerly widespread, now rare through much of range.
- *Eacles imperialis pini* Imperial moth One collected Grand Isle, '01; Chittenden Co. historically. Declined drastically or disappeared from VT in '50's. Also known from northern NY and southern Canada.
- *Hemileuca lucina* New England buckmoth Restricted to New England; found in SE VT.
- *Sphinx drupiferarum* Plum sphinx or Wild cherry spinx Reported from Franklin, Chittenden, Bennington, Orleans, and Lamoille counties. Populations declining in Eastern NA; uncommon to rare throughout range. Drastically reduced/extirpated over much of range.
- *Sphinx eremitus* Hermit sphinx Reported from Franklin, Windsor, and Grand Isle counties. Populations declining rangewide.
- *Sphinx luscitiosa* Clemens' sphinx Populations declining rangewide. Uncommon or rare throughout Northeast.
- *Lasionycta taigata* A noctuid moth Reported from Essex Co. '75 (Moose Pond).
- *Lithophane franclemonti* Franclemont's lithophane Known from one Grand Isle specimen.
- *Pachypolia atricornis* An autumnal noctuid moth Reported from Chittenden Co. (Proctor Maple Research Forest). Very rarely collected throughout range.
- *Papaipema sp. 2* Ostrich fern borer moth Rare outside of VT.
- *Properigea sp. 1* (P. costa) A noctuid moth Collected in Chittenden Co. Globally rare (G2G3).

### Habitat Description:

Habitat Information is based on the following:

- **Limited Local Knowledge**
- **Extensive Local Knowledge**
- **Regional Literature**
- **General Literature**

The following species:

- **Sthenopis thule** A ghost moth Single specimen, South Hero in '92. LFP*: reported on willows, but not well known.
- **Itame ribearia** Currant spanworm Collected Bakersfield, '91 (Franklin Co). LFP: currant, gooseberry. Forests, woodlands, wooded swamps. Formerly widespread, now rare through much of range due to eradication of currant in 1920's-'60's (alternate host of white pine blister rust).
- **Eacles imperialis pini** Imperial moth One collected Grand Isle, '01; Chittenden Co. historically. White pine specialist; possibly also pitch pine. Found in coniferous forest. Declined drastically or disappeared from VT in 1950's. Probable cause of decline was pesticide spraying and release of Compsilura concinnata for gypsy moth control. Use of BTK is also potential problem if used wrong time of year (late June or later).
- **Hemileuca lucina** New England buckmoth Restricted to New England; found in SE VT. Found in wet meadows and open fields. LFP: oak, Prunus serotina, willows, gray birch, Vaccinium; early instars on meadowsweet.
- **Sphinx drupiferarum** Plum sphinx or Wild cherry spinx Reported from Franklin, Chittenden, Bennington, Orleans, and Lamoille counties. Populations declining in Eastern NA; uncommon to rare throughout range. Drastically reduced/extirpated over much of range, reportedly due to aerial (DDT) spraying. Found in wooded habitats and suburbs. LFP: cherry, plum, apple; also lilac and hackberry.
- **Sphinx eremitus** Hermit sphinx Reported from Franklin, Windsor,and Grand Isle counties. Populations declining rangewide. LFP: Monarda, Mentha, Lycopus, Salvia.
- **Sphinx luscitiosa** Clemens' sphinx Populations declining rangewide. Uncommon or rare throughout Northeast. LFP: willow, poplar, birch, apple, ash.
- **Lasionycta taigata** A noctuid moth Reported from Essex Co. ’75 (Moose Pond). A bog associate.
- **Lemmeria digitalis** A noctuid moth Several collected in Chittenden Co., 1991-93.
- **Lithophane franclemonti** Francolemont's lithophane Known from one Grand Isle specimen. LFP and habitat unknown.
- **Pachypolia atricornis** An autumnal noctuid moth Reported from Chittenden Co. (Proctor Maple Research Forest). Very rarely collected throughout range. Found in mesic northern hardwoods with non-acidic soils.
- **Papaipema sp. 2** Ostrich fern borer moth Rare outside of VT. Responsibility species. Metapopulation structure is needed for long-term viability. Globally rare (G3G4).
- **Properigea sp. 1 (P. costa)** A noctuid moth Collected in Chittenden Co. Associated with shale, granite, or limestone barrens. Globally rare (G2G3).

Xestia fabulosa A noctuid moth Range not well-known. Recorded from VT, NH, and ON. LFP: Vaccinium sp.
Xestia homogena A noctuid moth Found in alpine habitat (high elevation; mountain peaks).
Zale submediana Gray spring zale Reported from Jericho Research Forest (Chittenden Co.) in ’90. Very rare in VT; probably was previously common in sand plains. LFP: jack, pitch, red, and probably other hard pines.
Zanclognatha martha Pine barrens zanclognatha Reported from Jericho Research Forest (Chittenden Co.) in ’90. Somewhat rare outside of NJ. Found in pitch pine/ scrub oak barrens in PA northward; Jericho population may have colonized pines from a remnant pine barren.

* LFP is larval food plant.

</tbody>
</table>
This group consists of several species, the habitat requirements of which vary within the general rivers/streams category. Most species have not been assigned state status ranks, due to incomplete distribution and abundance information, but records for each are very limited. Habitats given for each species refer primarily to reproduction and nymphal requirements; adults of many species depend on various nearby terrestrial habitats as well. Some dragonflies are known to exhibit "hilltopping" behavior, in which they congregate on tops of hills, which may be fairly distant from egg-laying sites. This would increase the home range requirements for such species.

American Rubyspot (Hetaerina americana)  Streams and rivers with emergent vegetation
Blue-fronted Dancer (Argia apicalis)  Small to large rivers with sand or mud; occasionally ponds and lakes
Rainbow Bluet (Enallagma antennatum)  Slow streams
Spine-crowned Clubtail (Gomphus abbreviatus)  Rivers
Rapids Clubtail (Gomphus quadricolor)  Large streams and rivers
Skillet Clubtail (Gomphus ventricosus)  Large rivers; mud or sand bottom
Cobra Clubtail (Gomphus vastus)  Large rivers with mud bottom; sometimes large streams and lakes
Brook Snaketail (Ophiogomphus aspersus)  Sandy streams
Riffle Snaketail (Ophiogomphus carolus)  Rapid, rocky or sandy streams and rivers
Maine Snaketail (Ophiogomphus mainensis)  Clear, rocky forested streams
Rusty Snaketail (Ophiogomphus rupinsulensis)  Rapid large streams and rivers
Riverine Clubtail (Stylurus amnicola)  Rivers
Zebra Clubtail (Stylurus scudderi)  Rivers
Stygian Shadowdragon (Neurocordulia yamaskanensis)  Large rivers and lakes; often rocky
**Distribution:**

- **American Rubyspot (Hetaerina americana)** streams and rivers with emergent vegetation
- **Blue-fronted Dancer (Argia apicalis)** small to large rivers with sand or mud; occasionally ponds and lakes
- **Rainbow Bluet (Enallagma antennatum)** slow streams
- **Spine-crowned Clubtail (Gomphus abbreviatus)** Windham
- **Rapids Clubtail (Gomphus quadricolor)** Rutland
- **Skillet Clubtail (Gomphus ventricosus)** Windham
- **Cobra Clubtail (Gomphus vastus)** Windham
- **Brook Snaketail (Ophiogomphus aspersus)** Rutland, Orange, Grand Isle, Orleans, Essex
- **Riffle Snaketail (Ophiogomphus carolus)** Windsor, Essex
- **Maine Snaketail (Ophiogomphus mainensis)** Bennington, Rutland, Chittenden, Caledonia, Orleans, Essex
- **Rusty Snaketail (Ophiogomphus rupinsulensis)** Windsor
- **Riverine Clubtail (Stylurus amnicola)** Windham
- **Zebra Clubtail (Stylurus scudderi)** Washington, Caledonia, Essex, Windsor

**Assessment Narrative:**

One species in this group: Gray petaltail (*Tachopteryx thoreyi*). Only a single, small population is known in Vermont. This is a rare species within the state, with specialized habitat requirements.

Current records for this species indicate that it is very rare. Greater effort is needed to located specific populations for conservation action. Habitat description refers primarily to reproduction and nymphal requirements; adults require adjacent, forested upland habitat as well. Some dragonflies are known to exhibit "hilltopping" behavior, in which they congregate on tops of hills, which may be fairly distant from egg-laying sites. This would increase the home range requirements for such species. Although placed in the wetland odonates group, the Citrine forktail (*Ischnura hastata*) will also use forested seeps.

**Assessment Narrative:**

This group includes three state-threatened species, one of which is also federally threatened, and three rare species, two of which are known from only one or two collections. Two of these beetles are likely extirpated.

Boulder beach tiger beetle (Cicindela anocisconensis) This rarely observed beetle is known from only single collections on two widely separated rivers. Return visits have not relocated this species. It is ranked S1 and is globally rare (G3).

Beach dune tiger beetle (Cicindela hirticollis) This state-threatened beetle's habitat and range has been greatly reduced in Vermont. It was formerly known from several sites along the northern Lake Champlain shores, but is now reduced to a single site. This habitat is fortunately protected by the Winooski Valley Park District.

Long-lip tiger beetle (Cicindela longilabris) Little is known about this species in Vermont. It is rarely collected, but more survey work is badly needed. It is ranked S2.

Cobblestone tiger beetle (Cicindela marginipennis) This state-threatened species has been studied in Vermont to a greater degree than other Cicindela species. Habitat losses along the Connecticut River and possibly other rivers have been significant due to impoundments.

Patterned green tiger beetle (Cicindela patruela) This is a very rare species throughout the Northeast and is known from a single Vermont collection made in 1870. It is also globally rare (G3). This species has probably gone the way of Vermont's sandplains; some habitat still remains that should be surveyed for this species and/or considered for reintroduction.

Puritan tiger beetle (Cicindela puritana) This federally threatened species is only known historically from a single Vermont site, although other historic sites were known along the New Hampshire side of the river. Impoundments along the Connecticut River likely caused the extirpation of this species. Other habitat losses may have also been a factor. Reintroduction could be considered if sufficient habitat improvements are made. Riverside recreational use has had a significant impact on populations at other New England sites.
Common Name: Tiger Beetles Group
Scientific Name: Tiger Beetles Group

Distribution Summary:
C. patruela Champlain valley. One historical site (Burlington).
C. anocisconensis West River (Jamaica) and White River.
Southern Green Mtns and possibly Southern Vermont Piedmont.
C. puritana Historically along lower portion of Connecticut River.
Hartland, VT and nearby NH sites.
C. hirticollis Champlain valley. Along Lake Champlain shoreline.
Current: Colchester; historical: 4 additional sites.
C. longilabris Northeast Highlands and near edge between
Champlain Valley/ Northern Green Mtns.
C. marginipennis Lower Connecticut River, White River, West
River, and single Winooski River. Southern Vermont Piedmont
and Northern Green Mtns.

Known Watersheds
CT-Bellows Falls Dam to Vernon Dam
CT-White River to Bellows Falls
Lake Champlain Direct
White River
Winooski River

Habitat Description:

Habitat Information is based on the following:
- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Boulder beach tiger beetle (Cicindela anocisconensis) Beetle is found along the margins of clear, clean
permanent streams of mid-sized rivers with some degree of shading. The adults prefer sandy areas near the
water, sometimes intermixed with cobbles, but always lacking vegetation. Larvae are found mostly in sandy-loam
soil that is often some distance from the water’s edge.

Beach dune tiger beetle (Cicindela hirticollis) This species is found on the sandy beaches formed at the mouths
and shores along large rivers emiting into the lake. Larvae burrow in moist sand in protected areas where there
is little wave action.

Long-lip tiger beetle (Cicindela longilabris) This beetle is found near bogs on sand or fine gravel soil, and on
Common Name: Tiger Beetles Group  
Scientific Name: Tiger Beetles Group  
Species Group: Invert

Bare rock ledges in the mountains. It is also found in sandy areas with mucky dark soil in or adjacent to coniferous forest. It occurs among jack pine, blueberries, and reindeer moss, often collected along abandoned or seldom-used sandy roads and other sandy gaps in coniferous forests. It has been reported from above tree line in the White Mountains, including the summit of Mt. Washington.

Cobblestone tiger beetle (Cicindela marginipennis) Species is in extremely restricted habitat, being found on cobble beaches of shores and islands of large rivers. Adults inhabit areas of cobble and sand where vegetation is very sparse. Larvae occupy burrows in the sand along the edges of cobblestones.

Patterned green tiger beetle (Cicindela patruela) This species occurs on sandy soil where jack pine, oak, blueberry, and sweet fern grow. Reported to occur along sandy roads and other coarse-grained sandy areas. Known elsewhere from pine-oak or other dry woodlands.

Puritan tiger beetle (Cicindela puritana) This species prefers wide sand deposits along big rivers or narrow beaches along rivers with clay banks.

</thead>
<tbody>
<tr>
<td>Research</td>
<td>Habitat Requirements</td>
<td>High</td>
<td>Define particular habitat requirements of each species within Vermont, utilizing current knowledge of researchers and field investigations.</td>
</tr>
<tr>
<td>Research</td>
<td>Distribution and Abundance</td>
<td>High</td>
<td>1) Conduct inventories to detect and gather information on SGCN tiger beetles. 2) Obtain baseline distributional and abundance data for all species in group by conducting surveys throughout the state. Efforts should be focused on particular habitats required by each. Abundance information should be collected at sites of known occurrence.</td>
</tr>
<tr>
<td>Research</td>
<td>Threats and Their Significance</td>
<td>High</td>
<td>1) Assess potential and existing impacts of limiting factors to habitat. Such limiting factors as habitat loss and degradation, exotic invasive plants, incompatible recreation, and dams should be examined. 2) Investigate how rivershore tiger beetle populations are being affected by dams and actions that can be taken to restore or mimic natural processes that maintain habitat.</td>
</tr>
</tbody>
</table>

Monitoring Population Change High  
1) Monitor known SGCN tiger beetle populations. 2) Population monitoring could be employed to track population trends at distinct locations. This would follow field surveys and assessments to identify populations judged to be large and viable. Focusing on such large populations would offer greater probability of detecting population shifts. Areas of habitat where species have disappeared need to be tracked.

Monitoring Habitat Change High  
Monitor change in available habitat for each species' specific requirements. Loss, restoration, and other changes to local habitat sites recognized as important to these species should be tracked.

Monitoring Monitor Threats High  
Recreational use of shoreline habitat needs to be monitored, as it can affect several species.

Species Strategies (see Appendix B for additional habitat, community & landscape conservation summaries.)

</tbody>
</table>

**Assessment Narrative:**

Individual species in this group are rare in Vermont; several are regionally or globally rare.

This group consists of two species, the habitat requirements of which vary. Species have not been assigned state status ranks, due to incomplete distribution and abundance information; records for each are very limited. Habitats given for each species refer primarily to reproduction and nymphal requirements; adults of many species require various nearby terrestrial habitats as well. Some dragonflies are known to exhibit "hilltopping" behavior, in which they congregate on tops of hills, which may be fairly distant from egg-laying sites. This would increase the home range requirements for such species. Although assigned to the wetland odonates group, the Southern spreadwing (Lestes disjunctus australis) and Citrine forktail (Ischnura hastata) will also utilize vernal pools for reproduction and early development.

Comet darter (Anax longipes) vernal pools and semi-permanent ponds (no fish)  
Painted skimmer (Libellula semifasciata) Marshy forested ponds, vernal pools, slow streams and bogs

### Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

This group consists of several species, the habitat requirements of which vary within the general hardwood forest category. Most species have not been assigned state status ranks, due to incomplete distribution and abundance information, but records for each are very limited. Caterpillars require specific food plants, which are referenced below.

- **Bog copper** (*Lycaena epixanthe*): Acid bogs with cranberry and other Ericaceae. Host plants are cranberries.
- **Jutta arctic** (*Oeneis jutta*): Acid spruce bogs. Host plant is cottongrass (*Eriophorum spissum*).
- **Dion skipper** (*Euphyes dion*): Calcareous fens and other alkaline to neutral wetlands. Host plants are various sedges including *Scirpus cyperinus*, *Carex lacustris*, and *Carex hyalinolepis*.
- **Black dash** (*Euphyes conspicua*): Wet meadows and marshes. Host plant is *Carex stricta* and possibly other *Carex*.
- **Two-spotted skipper** (*Euphys bimacula*): Wet acid-soil areas such as bogs, acidic marshes, and meadows. Host plant is *Carex trichocarpa*.
- **Mulberry wing** (*Poanes massasoit*): Wet meadows, open marshes, fens, or bogs. Host plant is *Carex stricta*, possibly other *Carex*.
- **Broad-winged skipper** (*Poanes viator*): Marshes. Host plant is *Carex lacustris*.

Common Name: Northern bog lemming  
Scientific Name: Synaptomys borealis  
Species Group: Mammal

**Conservation Assessment:**

- **Final Assessment:** High Priority
- **Global Rank:** G4
- **Global Trend:** Unknown
- **State Rank:** SU
- **State Trend:** Unknown
- **Exirpated in VT?** No
- **Regionally Rare?** N/A

**Assessment Narrative:**

There is no historical or recent evidence that the Northern bog lemming was ever in Vermont, but Vermont is bracketed by a population in NY (1 specimen from Whiteface Mountain) and New Hampshire (Coos County, Mt Moosalacka 1996), Maine (3 specimens from Baxter State Park) and Quebec. Vermont appears to have viable habitat.

**Distribution Summary:**

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge ✔
- Extensive Local Knowledge ☐
- Regional Literature ☐
- General Literature ☐

In the Adirondacks, Maine and New Hampshire the northern bog lemming is found in conifer forests often associated with sphagnum. They require moist loose soils with sphagnum (DeGraff and Yamasaki, 1986). Northern bog lemmings feed on the succulent parts of grasses as well as seeds and fungi and use burrows several inches below the ground (DeGraff and Yamasaki, 1986).
Common Name: Northern bog lemming  
Scientific Name: Synaptomys borealis  
Species Group: Mammal

### General Habitat Preferences:
- **Minimum Elevation (m):** 330
- **Maximum Elevation (m):** 1375
- **Patch Size Requirements:** Unknown
- **Preters large wetland complexes:** No
- **Preters large expanses of grassland habitat:** No
- **Preters habitat mosaics:** No
- **Preters developed landscapes:** No
- **Preters actively managed woodland:** No
- **Requires movement corridors:** No
- **Preters large expanses of forest habitat:** No

### Vegetation Categories Used:
- Open Peatlands
- Outcrops and Alpine
- Softwood Swamps
- Spruce Fir Northern Hardwood

### Current Problems: (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Climate Change
- Conversion of Habitat
- Impacts of Roads or Trails

**Description of habitat problem(s):** Habitat conversion that results in the elimination of peatlands is a problem to the n. bog lemming. Climate change that results in increasing temperatures, could result in could be an increase in the meadow mouse population which could compete with n. bog lemmings. Development of roads, trails and powerlines could also provide access for meadow mouse populations and result in increased competition with the n. bog lemming.

**Non-Habitat Problems:**
- Competition

**Description of non-habitat problem(s):** Habitat changes that benefit the meadow mouse could result in increased competition that negatively affects the northern bog lemming.

Species Group: Mammal

Conservation Assessment:
Final Assessment: Medium Priority
Global Rank: G5
State Rank: S5
Global Trend: Unknown
State Trend: Unknown
Exterminated in VT? NA
Regionally Rare? No

Assessment Narrative:
S5 G5 State trend is unknown. May be the most common of the small shrews but still relatively rare at most locations. May be more common at higher elevations but the role of elevation is unclear. More common in old growth or late successional forests.

There is insufficient data on the status of this species. Considered rare though very broadly distributed.

Distribution Summary:
Considered rare though broadly distributed.

Habitat Description:
Habitat Information is based on the following:
Limited Local Knowledge ✓ Extensive Local Knowledge ✓ Regional Literature ✓ General Literature ✓

Cool mesic deciduous and coniferous forests often at higher elevations. Sometimes found in mixed habitat types such as edges of bogs and other cool and wet sites (seeps). The masked shrew uses grasses, rocks, and logs or stumps for cover. They are primarily carnivorous and insectivorous consuming worms, spiders, snails, slugs, and small amounts of vegetable matter. Dampness of site and depth of leaf litter, seems to be critical factors in determining habitat use.

down woody debris
Common Name: Cinereus or Masked Shrew  
Scientific Name: Sorex cinereus  
Species Group: Mammal

### General Habitat Preferences:
- Minimum Elevation (m): 200

### Current Problems: (see Appendix C for definitions of problem categories)

#### Habitat Problems:
- Unknown Habitat Threats

  **Description of habitat problem(s):** Alterations to the habitat that dries out the site could negatively affect this shrew.

#### Non-Habitat Problems:
- Competition
- Loss of Prey Base
**Common Name:** Cinereus or Masked Shrew  
**Scientific Name:** Sorex cinereus  
**Species Group:** Mammal

Pollution  
Trampling or Direct Impacts  
Unknown Non-Habitat Threats

**Description of non-habitat problem(s):** Competition from other shrews has been shown in the literature to put this shrew at risk. Loss of prey base may be caused by acid rain altering soil invertebrates.

**Conservation Assessment:**

**Final Assessment:** High Priority  
**Global Rank:** G5  
**Global Trend:**  
**State Rank:** S3  
**State Trend:** unknown  
**Extirpated in VT?** no  
**Regionally Rare?** yes  

**Assessment Narrative:**

State trend: very limited data. Fifty five specimens taken since 1915 (pers com W. Kilpatrick) from 19 different localities.

Species is listed as a high priority because not a lot is known about it, and it has very specific habitat needs. There is no evidence of a decline because there are so few records of it. Acid rain could be a significant problem. We believe that at present there are limited localized at risk populations but the data too limited to determine status. There are taxonomic uncertainties: Is it actually more than one species? Potential limiting factors include flooding, water movement, ice movement, dams/flow regulation, clearcut w/o buffers, atmospheric deposition, loss of habitat, decline in hab quality, roads & trails, potential loss of prey base.

**Distribution Summary:**

55 specimens have been taken in Vermont since 1915.

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge  
- Extensive Local Knowledge
- Regional Literature
- General Literature

Found in undercut banks of streams and beaver dams. We assume that wooded buffers on streams are desirable. Wooded wetlands and streams are utilized over cattail wetlands. Mesic forests are important. Has been trapped on dry creekbeds but may prefer streams that flow year-round. DeGraaf (2001) suggests that coniferous forests are preferred over deciduous forests. Whitiker & Hamilton found this species on mud flats of sluggish backwaters. D. Andrew Saunders suggests that habitats adjacent to water, particularly fast cold...
Sorex palustris  
Water Shrew

Species Group: Mammal

Streams may hold the largest populations. Critical habitat appears to be undercut banks of streams and possibly beaver dams.

undercut stream banks and beaver seeps

**General Habitat Preferences:**

- Minimum Elevation (m): 150
- Maximum Elevation (m): 1300
- Patch Size Requirements: Unknown
- Prefers large wetland complexes: [ ]
- Prefers large expanses of grassland habitat: [ ]
- Prefers habitat mosaics: [ ]
- Prefers developed landscapes: [ ]
- Prefers actively managed woodland: [ ]
- Requires movement corridors: [ ]
- Prefers large expanses of forest habitat: [ ]

**Vegetation Categories Used:**

- Aquatic: Fluvial
- Floodplain Forests
- Marshes and Sedge Meadows
- Open Peatlands
- Shrub Swamps
- Spruce Fir Northern Hardwood
- Wet Shores

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Conversion of Habitat
- Habitat Alteration
- Impacts of Roads or Trails
- Inadequate Disturbance Regime

*Description of habitat problem(s):* Clear cutting adjacent to stream that results in the conversion of the forested buffer could cause warming, sloughing and habitat degradation that impacts survival and productivity.

Flooding (disturbance) may be important to keep the banks of streams undercut. Lack of baseline data exists for distribution, abundance and basic life-history

**Non-Habitat Problems:**

- Loss of Prey Base
- Pollution

*Description of non-habitat problem(s):* Loss of prey base due to acid rain is a potential problem.

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Often occupies damp, boulder-strewn, upland woods (DeGraff and Yamasaki 2001). Found in cool mesic forests, often conifer, that are shady with deep, loose, leaf litter. Often occupies coniferous, higher elevation sites with damp, moss covered rocks. Requires dead and down logs for cover and foraging. Typically found along streams with moss covered banks (DeGraff and Yamasaki 2001). Diet is 80 % insectivorous but will also eat earthworms, spiders, snails, salamanders, small mammals, and birds. The dietary niche of the smoky shrew is broader than that of other shrews (Bramon 2000). Uses tunnels made by other animals for nesting as well as beneath stumps and rotten logs. Loose damp leaf litter may be critical to habitat use.

Common Name: Long-tailed or Rock Shrew  
Scientific Name: Sorex dispar  
Species Group: Mammal

**Conservation Assessment:**

**Final Assessment:** High Priority  
**Global Rank:** G4  
**State Rank:** S2  
**Global Trend:** unknown  
**State Trend:** unknown  
**Extirpated in VT?** No  
**Regionally Rare?** yes

**Assessment Narrative:**

Sorex dispar is listed as an S2 species in Vermont. Total number of state occurrences is 17 (Tumosa 2001) but most of those were reported prior to 1940. Only 6 specimens have been taken since 1972 and there have been no known specimens since 1989. Currently listed as C-2 species by USFWS indicating that the species may be endangered or threatened but insufficient information is currently available to allow preparation of rules to list the species. (Chipman, 1994 in Tomosa 2001)

Limited localized at risk population with data too limited to determine status. One female was collected in stunted spruce/fir habitat in Stowe (Chipman 1994, VT Natural Heritage database). Three long-tailed shrews were captured at 3 sites in the Green Mountain biophysical region--2 on top of Mt. Manfield and one in a hardwood stand adjacent to a high elevation lake (Chipman 1994 in Tomosa 2001)

**Distribution Summary:**

Found in the Mendon-Wallingford area of the Southern Green Mountains

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge ☑
- Extensive Local Knowledge ☐
- Regional Literature ☐
- General Literature ☐

Prefers cold, mesic forests, typically coniferous, near streams especially with undercut stream banks. The rock shrew often inhabits cool, mossy talus slopes and rocky moss covered boulders and logs. Moss-covered rocks and logs that provide shade and protective crevices or wooded talus slopes are also important. May also be found in deciduous and mixed forests. Rocky, loose talus, dead woody debris and open understories may be critical to the long-tailed shrew. May be associated with rock vole. They seem to spend most of their time in

the labyrinth of spaces between rocks about a foot beneath the surface (Kirkland 1981).  
undercuts of banks, presence of rock vole, Talus slopes

**General Habitat Preferences:**

- Minimum Elevation (m): 150
- Maximum Elevation (m): 1350
- Requires movement corridors: Unknown
- Prefers large wetland complexes: No
- Prefers large expanses of grassland habitat: No
- Prefers habitat mosaics: No
- Prefers developed landscapes: No
- Prefers actively managed woodland: No
- Requires movement corridors: No
- Prefers large expanses of forest habitat: Yes

**Vegetation Categories Used:**

- Cliffs and Talus
- Northern Hardwood
- Spruce Fir Northern Hardwood

### Current Problems: (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Conversion of Habitat
  - **Description of habitat problem(s):** Ski trails and associated structures could impact the habitat of the long-tailed shrew. Conversion of habitat as a result of quarrying activities could also destroy critical rocky, talus habitat.

**Non-Habitat Problems:**

- Loss of Prey Base
- Pollution
  - **Description of non-habitat problem(s):** Change in prey base due to acid rain deposition at high elevations. Shrews feed on invertebrates and therefore may accumulate pesticides and heavy metals in body tissue (Tumosa 2001). Mining, mercury deposition, and the application of sewage sludge can all negatively affect long-tailed shrews due to a build up of toxins in the body.

**Distribution Summary:**

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge  
- Extensive Local Knowledge  
- Regional Literature  
- General Literature

Habitat requirements are relatively unknown. It is believed that mesic forests and fields are used but it has also been recorded in swamps and marshes. Critical habitat is often listed as boreal forests where wet and dry areas occur together. Disturbed sites and cultivated areas with leaf litter and downed logs may also be used. Believed to require moist leaf mold near water (DeGraff and Yamasaki, 2001). Usually found within 100yds of water. There is no evidence in the literature that it prefers any particular forest age class. It was found in 4 different age classes of cove hardwood stands in southern Appalachia (Ford et al. 1996 in Tumosa 2001). bogs, mesic forest w/deep leaf litter, sandy & sandy loam well-drained soils (Miller, Caledonia Co)

Distribution Summary:

Habitat Description:

Habitat Information is based on the following:

Limited Local Knowledge ✓ Extensive Local KnowledgeRegional Literature ✓ General Literature ✓

Found in all places with well-drained sandy loam soils (e.g. agricultural fields and older forests). Open deciduous woodlands with thick humus are preferred. Hairy-tailed moles are also adapted to second growth stands, old fields, and hedgerows. They prefer well-drained, light, moist soil with well-mixed organic matter and minerals and avoid soils that are hard, dry, or with a large clay content.

sandy/sandy loam soils
Common Name: Hairy-tailed Mole
Scientific Name: Parascalops breweri

Species Group: Mammal

Conservation Assessment:
Final Assessment: Medium Priority
Global Rank: G5
State Rank: S5
Global Trend: Declining
State Trend: Declining
Exirpated in VT? No
Regionally Rare? No

Assessment Narrative:
Presently considered to be relatively common but relies heavily on human dwellings as maternity sites. It is unclear as to what its native habitat is. Both maternity colony habitat and winter hibernacula are vulnerable and at risk. Every year bats lose hundreds of possible building roosts as results of exclusion or the actual removal of old barns and other structures. No attempts have been made to inventory maternity colonies in Vermont.

Although little brown bats are known to hibernate in slightly greater than 20 sites in Vermont, the vast majority of the population hibernate in a single cave. Little brown bats may also be impacted by the removal or killing of bats by pest control agents, as well as, recreational spelunking in hibernacula. Trend information is needed on this species.

Distribution:

  - Within Region: No
  - Within US: No
  - Outside US: No

Habitat Description:
Habitat Information is based on the following:
- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

The little brown bat prefers warmer and more humid areas where the temperature is constant. To prevent dehydration they awaken every ten to fourteen days to consume water. Little brown bats often hibernate in large clusters. This is thought to act as a buffer against water loss, enabling longer hibernation between arousals (Sanders 2004). During the summer it often inhabits attics where the temperature may average 100 degrees (Chenger 2004). Females may form nursery colonies of hundreds or even thousands of individuals. It is unclear where most of the males spend the summer months but it is assumed they are solitary. Colonies
usually exist close to water because little brown bats seem to prefer to forage over water. When foraging, the bats may repeat a set hunting pattern within a few miles of the roost (Chenger 2004). Little brown bats eat moths, wasps, gnats, crane flies, and beetles. Young are born in May, June, or early July. Average litter size is one. In winter little brown bats hibernate in caves with a constant temperature of 40 degrees F and a relative humidity of 80% (Banfield 1974: 42 in DeGraff and Yamasaki, 2001)

**General Habitat Preferences:**

- Minimum Elevation (m): 0

Mine
Northern Hardwood
Oak-Pine Northern Hardwood
Open Peatlands
Shrub Swamps
Spruce Fir Northern Hardwood
Subterranean
Wet Shores

**Current Problems:** *(see Appendix C for definitions of problem categories)*

**Habitat Problems:**

Conversion of Habitat
Habitat Alteration

*Description of habitat problem(s):* disturbance in hibernacula reduces fat reserves and negatively affects reproduction and survivability. In addition, every year big and little brown bats lose hundreds of possible building roosts due to exclusion or the actual destruction of buildings. Direct killing of bats is common due to human fears about rabies, bat bites and histoplasmosis.

**Non-Habitat Problems:**

Pollution

*Description of non-habitat problem(s):* Pesticides and environmental poisons have had negative impacts on, and increased the mortality rates of, bat populations. Bats store some lipophilic pesticides in brown adipose fat tissues. These stores are released as bats use their fat reserves during hibernation. Depending upon tissue levels of the pesticide, as well as the amount of fat used over a given time period, bats can be exposed to both chronic and acute poisoning which can result in death. At lower levels, chronic poisoning may raise a bat's metabolism, burning the limited fat resources more quickly and possibly causing them to starve to death. In addition, broad spectrum insecticides can deplete insect diversity and limit the food sources available for bats.

Final Assessment: High Priority  
Global Rank: G2  
State Rank: S1  
Global Trend: Stable  
State Trend: Stable  
Extirpated in VT? No  
Regionally Rare? Yes

**Assessment Narrative:**

Indiana bats are listed as endangered in Vermont. They have declined range wide by 60% since monitoring began in the 1960's. Historic numbers were estimated at 800,000 in the late 1960's and by 1997 the range wide population was down to 350,000 (USFWS, 1999 in Sanders, 2004). Recent surveys indicate that regionally the population may be rebounding and possibly increasing.

In Vermont in the 1940-50s, Indiana bats were reported in the 1000s in hibernacula. In recent years a couple of hundred have been documented. For some reason this bat is declining nationally. It isn't known why, but could be related to disturbance in the hibernacula. Limited dispersal may be a problem for pregnant females. Vermont is the only New England state known to harbor maternity colonies. Radio collared Indiana bats roosting in the Champlain Valley came from hibernacula in New York (Sanders, 2004). Vermont also has three hibernacula currently used by Indiana bats: Brandon Silver Mine (159 bats in 2002), Littlw Skinner Hollow (297 bats in 2004), and Dorset Cave (16 bats in 2003). Historic hibernacula include the Plymouth Caves, Nickwackett Cave, and the Ely Copper Mine.

**Current Problems:**
(see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Alteration

**Description of habitat problem(s):** Disturbance of winter hibernacula is a significant problem to Indiana bats. These bats have been documented to lose 15-20% of their body weight during hibernation in an undisturbed hibernaculum (Johnson et al. 1997, in Sanders, 2004). Disturbance of hibernating bats causes them to awaken and forces them to use additional limited energy reserves (Sanders, 2004). Arousal can use up enough fat to sustain a bat for 10-30 days (Thomas et al. 1990, Thomas 1995). Changes in temperature and light, as well as, direct contact can cause a bat to awaken and deplete stored fat reserves. Alterations to cave mine openings can change the microclimate of a mine and affect bat survival. Loss of maternity roosts may also be a problem to survivability of young. Maternity roosts can house several hundred individual bats. Felling of a maternity roost tree can impact the survival of both adults and young. Development within close proximity of hibernacula, particularly along travel corridors could also be detrimental to survival. Destruction/development of summer habitats are likely to negatively affect bats if potential roost sites and foraging areas are altered (Tumosa 2003).
Non-Habitat Problems:

Pollution

*Description of non-habitat problem(s):* Pesticides and environmental poisons have had negative impacts on, and increased the mortality rates of, bat populations. Bats store some lipophilic pesticides in brown adipose fat tissues. These stores are released as bats use their fat reserves during hibernation. Depending upon tissue levels of the pesticide, as well as the amount of fat used over a given time period, bats can be exposed to both chronic and acute poisoning which can result in death. At lower levels, chronic poisoning may raise a bat's metabolism, burning the limited fat resources more quickly and possibly causing them to starve to death. In addition, broad spectrum insecticides can deplete insect diversity and limit the food sources available for bats.

**State Rank:** S1  
**Global Trend:** unknown  
**State Trend:** unknown  
**Extirpated in VT?** No  
**Regionally Rare?** yes

**Assessment Narrative:**

Status: S1, On the threatened list in Vermont. Regionally it seems to be at risk. The small-footed bat is listed as endangered in New Hampshire and a species of concern in Maine. It seems to be fairly widespread in SE Canada and the eastern U.S. but is found in very low numbers.

There is a general lack of information about this species. It may hibernate outside the major hibernacula in the state. It is found in small numbers in the major caves in Vermont. In 2004, 122 small-footed bats were counted in the Ely Copper Mine, a hibernaculum in Vermont. In 1991 Plymouth cave had a population of 16 (Tumosa 2003). Dorset cave had 2 individuals in 1992. Manchester had 1 individual in 1983 and the Vershire population seems to be highly variable but had 4 individuals in 2001. Danby in 1991 had 1 individual; Brandon had 4 individuals in 1999; Corinth had 2 individuals in 1993; and Sudbury had 17 individuals in 1999 (Natureserve 2003 in Tumosa 2003). Three small-footed bats were caught in mist nets in 2003 at the Union Village Dam, North Hartland dam, and Townshend dam (a female, male, and female respectively) by a contractpr for the US Army Corp of Engineers (Chenger 2003). There are summer records of this bat from Monkton, E. Middlebury, Lincoln, and Brandon mine (Kilpatrick, pers., com). This bat may be particularly susceptible to disturbance.

**Distribution Summary:**
Myotis leibii

Small-footed Bat

Species Group: Mammal

Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

In both winter and summer the small-footed bat is closely associated with rocky habitat such as caves, cliffs, talus piles, quarry faces, and rock outcrops. It hibernates in very cold sites, often in the entrance areas of caves and mines sometimes using small cracks or piles of breakdown on cave and mine floors. Hibernacula surveys probably undercount the species. They may also hibernate in talus piles and cliffs that have deep crevices; however, the extent of this behavior in Vermont is unknown. No maternity sites have been found in Vermont, however, in other states they use barns and buildings, cliffs and bridges, but are primarily found under exfoliating tree bark (Sanders 2004). Changer (2004) documented small-footed bats using crevices in rocks and large rip-rap on a man made dam face in New Hampshire. A radio-tansmittered small-footed bat was found to use power line corridors (Kilpatrick, pers com). Areas that promote an abundance of insects are crucial to small-footed bat survival (Tomosa, 2003). Beaver ponds with abundant snags may provide roosting and foraging sites.

General Habitat Preferences:

- Mine
- Other Cultural
- Subterranean

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:

- Climate Change
- Conversion of Habitat
- Habitat Alteration
- Impacts of Roads or Trails

Description of habitat problem(s): These bats may be more susceptible to disturbance in the hibernacula. Disturbance of hibernating bats causes them to awaken and forces them to use additional limited energy reserves (Sanders, 2004). Arousal can use up enough fat to sustain a bat for 10-30 days (Thomas et al., 1990; Thomas, 1995; Martin et al, 1966). Changes in temperature and light, as well as, direct contact can cause a bat to awaken and deplete stored fat reserves. Alterations to cave mine openings can change the microclimate of a mine and affect bat survival. Loss of maternity roosts may also be a problem to survivability of young. Little is known about the summer habitat requirements of this bat but destruction/development of summer habitats are likely to negatively affect bats if potential roost sites and foraging areas are altered (Tomosa 2003).
Warm winters and drought conditions are likely to increase bat body temperatures and corresponding metabolic demands which may influence survivability and reproduction.

**Non-Habitat Problems:**

Pollution

**Unknown Non-Habitat Threats**

*Description of non-habitat problem(s):* Insecticides and pesticides have been implicated in the decline of several bat species (Belwood 1998 in Tumosa 2003). Environmental poisons have had negative impacts on, and increased the mortality rates of, bat populations. Bats store some lipophilic pesticides in brown adipose fat tissues. These stores are released as bats use their fat reserves during hibernation. Depending upon tissue levels of the pesticide, as well as the amount of fat used over a given time period, bats can be exposed to both chronic and acute poisoning which can result in death. At lower levels, chronic poisoning may raise a bat's metabolism, burning the limited fat resources more quickly and possibly causing them to starve to death. In addition, broad spectrum insecticides can deplete insect diversity and limit the food sources available for bats.

Conservation Assessment:

**Final Assessment:** Medium Priority

**Global Rank:** G4

**State Rank:** S4S5

**Global Trend:** unknown

**Extirpated in VT?** No

**Regionally Rare?** No

Assessment Narrative:

Until recently the northern long-eared bat was considered uncommon. Recent surveys however, refute that assessment. A study done in 1992 and 1993 found that of 1310 bats captured at fall swarming sites, 12% were long-eareds (Thomas, 1992 in Sanders 2004). A 1999 mist net survey by the USFS (Thomas, 1999) found that 35 of 126 bats captured were northern long-eared bats, 14 of which were either adult or juvenile females. In 2000 a similar survey on the Green Mountain National Forest (Reynolds 2000a, 2000b) resulted in 16 of the 25 bats being northern long-eared. Several other summer surveys have been conducted in recent years for the Green Mountain National Forest and other entities in Vermont (Kiser et al, 2001, 2002; Reynolds, 2000; Kilpatrick 2001; Decker and Kilpatrick, 2002, 2003; Beverly et al., 2002)

Loss of maternity roosts could be a concern. Little information exists regarding summer roosting needs. Recreational spelunking could also affect winter survivability. Information is needed on population trends and recruitment.

State Rank: S2  
State Trend: Unknown

Exirpated in VT? no  
Regionally Rare? Yes

Assessment Narrative:

Status of this bat is unknown but presumed to be much lower than historical levels. Many factors could be influencing the decline. Silver-haired bats migrate along the eastern seaboard in winter and could encounter factors that affect its survival. In some parts of the country it is associated with late successional forests with a snag density of more than 21 snags/ hectare. Loss of forest habitat throughout the 1800's probably contributed to the decline of this bat in New England. Other factors such as pesticides, availability of prey, and loss of maternity roosts could also be influencing the status of this bat.

Once the most common bat in the region in the 1800s it has experienced a significant decline throughout the Northeast. Currently very rare. Two records in Vermont (Champlain Valley). This species is the shortest-lived (avg 2 years, maximum 12 years) and hence populations may be more sensitive to changes than other bat species. Perhaps this is a good indicator of bats in general.

Distribution:

- **Outside US**

**Distribution Summary:**

Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Silver-haired bats will range up to 5km from roost tree to forage areas. In summer, they roost under the bark of late- successional and old-growth boreal forests and perhaps along woodland edges. They forage in forest openings, including clear cuts, and over water and sometimes roost in buildings. In other parts of the country they are associated with late successional forests with snag densities of 21 snags /hectare. They form maternity
**Common Name:** Silver-haired Bat  
**Scientific Name:** Lasionycteris noctivagans  
**Species Group:** Mammal

Colonies almost exclusively in tree cavities and will periodically switch roosts throughout the maternity season. Like big brown bats, the silver-haired bats feed on many insect pest species such as flies, midges, leafhoppers, moths mosquitos, beetles, crane flies, lacewings caddis flies ants crickets, and spiders.

**General Habitat Preferences:**
- Minimum Elevation (m): 20
- Maximum Elevation (m): 2000
- Patch Size Requirements: Unknown
- Prefers large wetland complexes: Unknown
- Prefers large expanses of grassland habitat: Unknown
- Prefers habitat mosaics: Yes

- Aquatic: Lower CT River
- Early Succession Boreal Conifers
- Early Succession Boreal Hardwoods
- Early Succession Northern Hardwoods
- Early Succession Other Types
- Early Succession Pine and Hemlock
- Early Succession Spruce-Fir
- Early Succession Upland Oak
- Grasslands and Hedgerows
- Northern Hardwood
- Oak-Pine Northern Hardwood

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Alteration

**Description of habitat problem(s):** Conversion of forest habitat as a result of rural development that leads to loss of mature and older forests used as roosting habitat. Because silver-haired bats are migratory, they could be limited by wind and radio towers as well as powerlines. Predators include several kinds of birds including blue jays therefore increased suburbanization could increase loss to predation.

**Non-Habitat Problems:**
- Disease
- Loss of Prey Base
- Pollution

**Description of non-habitat problem(s):** Pesticides and environmental poisons have had negative impacts on, and increased the mortality rates of, bat populations. Bats store some lipophilic pesticides in brown adipose fat tissues. These stores are released as bats use their fat reserves during hibernation. Depending upon tissue levels of the pesticide, as well as the amount of fat used over a given time period, bats can be
exposed to both chronic and acute poisoning which can result in death. At lower levels, chronic poisoning may raise a bat's metabolism, burning the limited fat resources more quickly and possibly causing them to starve to death. In addition, broad spectrum insecticides can deplete insect diversity and limit the food sources available for bats. Silver-haired bats are also susceptible to a virulent strain of rabies.

**Exirpated in VT?** No  
**Regionally Rare?** Unknown

### Assessment Narrative:

One of the 6 species that overwinter in Vermont. The pipistrelle occur in small numbers in Vermont hibernacula and are only infrequently caught in mist net surveys. Its small size and multiple young (2 vs. 1 for most bats) makes it more vulnerable.

Little is known about this species, it appears uncommon but more data is needed. Approximately a dozen specimens have been found as a result of winter surveys and only one or two through summer surveys. May be at the northern edge of summer range.

The pipistrelle forages over wetlands, riparian areas, and forest edges, ingesting ants, moths, small beetles, mosquitoes and other insects. Possibly uses trees for maternity roosts, although in Vermont, the Eastern pipistrelle has not been found with other tree roosting bats. In Indiana they are found in sugar maple and American elms, as well as tulip and sycamore trees. The pipistrelle is also found in the dead foliage of oaks. They hibernate in caves mines and rock crevices where humidity is high and temperatures are around 10 to 15 degrees centigrade.

**Current Problems:**  (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Alteration

**Description of habitat problem(s):** Hibernating bats are limited by degradation, destruction and disturbance of hibernacula (caves and mines). Bats disturbed within the hibernacula use significant stores of fat each time they are awakened. If awakened enough times, bats can deplete their fat reserves and not have enough energy resources to complete spring migration, survive post emergence periods of bad weather or initiate and successfully complete gestation. In some cases, awakening hibernating bats can directly lead to their death. Closure of mines or caves in winter, when bats are present, would lead to the destruction of the entire colony. Slight alterations in cave/mine microclimate as a result of modifications to the opening etc. could also negatively impact hibernating bats. Removal of trees which serve as bat roosts, especially those serving as maternity roosts can directly kill entire colonies of bats. Wind energy turbines located on ridge tops have been found to directly kill bats as well.

**Non-Habitat Problems:**
- Pollution
- Trampling or Direct Impacts

**Description of non-habitat problem(s):** Pesticides and environmental poisons have had negative impacts on, and increased the mortality rates of, bat populations. Bats store some lipophilic pesticides in brown adipose fat tissues. These stores are released as bats use their fat reserves during hibernation. Depending upon levels of the pesticide in the tissue, as well as, the amount of fat used over a given time period, bats can be exposed to both chronic and acute poisoning which can result in death. At lower levels, chronic poisoning may raise a bat's metabolism, burning the limited fat resources more quickly and possibly causing them to starve to death. In addition, broad spectrum insecticides can deplete insect diversity and limit the food sources available for bats.

#### Assessment Narrative:

Population is listed as S4--apparently secure, but could decline in future as a result of impacts to hibernacula (cold caves and buildings). In addition, loss of summer maternity roosts (buildings and the same trees as those used by the Indiana bat) could cause a decline in numbers over time.

Because big brown bat maternity sites are most often in human structures such as barns, sheds, houses, and churches, they are frequently in conflict with people. At best, they may be excluded from these structures, forcing a split into several smaller maternity sites. At worst, they may be extirpated by pest control agents. Little is really known about the status of this bat or its population trends. Big brown bats are among the first bats to give birth and often have 2 offspring. Five Army Corp of Engineer (ACE) Vermont lakes were surveyed for bats the summer of 2003. Field inventories included mist netting, harp traps, and Ana Bat recordings between June 23 and July 14 and resampled July 25 and August 13. Ninety-nine males, 101 females and 16 unknown sex, big brown bats were captured with mist nets in the southern Connecticut River Valley (Chenger 2003).

    - General Literature

  In summer, big brown bats roost in the attics of churches, houses, and old abandoned structures and deciduous tree cavities. In winter they hibernate in very cold areas (cave entrances and cliff faces) often with temperatures very close to and sometimes below freezing. This is the only bat species in VT known to
Epotesicus fuscus

Common Name: Big Brown Bat
Scientific Name: Epotesicus fuscus
Species Group: Mammal

Brown bats hibernate in buildings. These low temperatures allow them to drastically slow their metabolism (Sanders 2004). Right now, big brown bats hibernate in fewer than 20 sites in Vermont. Big brown bats consume beetles, ants, flies, mosquitoes, mayflies, stoneflies, and other insects. They emerge from their summer roost at dusk and fly a steady, nearly straight course to foraging areas (Chenger, 2004). There may be fidelity to the feeding grounds and some bats use the same grounds night after night. Little is known about where these bat winter.

unknown

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
Conversion of Habitat
Habitat Alteration
Description of habitat problem(s): Every year big and little brown bats lose hundreds of possible building roosts due to exclusion or the actual destruction of buildings. Direct killing of bats is common due to human fears about rabies, bat bites and histoplasmosis. In addition, alterations or impacts to winter hibernacula also limits the future of this bat.

Non-Habitat Problems:
Pollution
Description of non-habitat problem(s): Pesticides and environmental poisons have had negative impacts on, and increased the mortality rates of, bat populations. Bats store some lipophilic pesticides in brown adipose fat tissues. These stores are released as bats use their fat reserves during hibernation. Depending upon levels of the pesticide in the tissue, as well as, the amount of fat used over a given time period, bats can be exposed to both chronic and acute poisoning which can result in death. At low levels, chronic poisoning may raise a bat's metabolism, burning the limited fat resources more quickly and possibly causing them to starve to death. In addition, broad spectrum insecticides can deplete insect diversity and limit the food sources available for bats.

- **Global Rank:** G5
- **Global Trend:** unknown
- **State Rank:** S3S4
- **State Trend:** unknown
- **Extirpated in VT?** no
- **Regionally Rare?** Unknown

**Assessment Narrative:**

Once one of the most abundant bats in many parts of their range, red bats appear to have declined dramatically over the last 100 years. Little is known about the Vermont population. Recent summer monitoring efforts (2003) in the upper Connecticut River Basin netted a total of 3 males and 1 female at Stoughton Pond in N. Springfield, Townshend Dam in Townshend, Townshend lake in Townshend, and Branch brook in Springfield respectively (Bat Conservation and Management, 2003).

The eastern red bat is a solitary rooster which often hangs by one foot from branches in the foliage appearing as dead leaves in the crown of the tree. It prefers older forests with dense canopy foliage and open understory as well as hedgerows with elms and eastern red cedar stands. They are fast flyers that forage in open areas along hedgerows and field edges. The eastern red bats migrate south to Gulf states to hibernate. Tree bats such as the red, silver-haired, and hoary are the least studied of the bats and little is known about their status or

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
Conversion of Habitat
Habitat Alteration

Description of habitat problem(s): Problems include conversion/degradation of forest habitat, as well as, rural development leading to loss of mature forest. Loss of American elms, a major roost tree, may be a continuing factor in the decline of the red bat. Because red bats are migratory, they could be limited by wind and radio towers as well as powerlines. Predators include several kinds of birds including blue jays therefore increased suburbanization could increase loss to predation.

Non-Habitat Problems:
Loss of Prey Base
Pollution

Description of non-habitat problem(s): Being migratory they could be limited by wind and radio towers and powerlines. Pesticides and environmental poisons have had negative impacts on, and increased the mortality rates of, bat populations. Bats store some lipophilic pesticides in brown adipose fat tissues. These stores are released as bats use their fat reserves during hibernation. Depending upon tissue levels of the pesticide, as well as the amount of fat used over a given time period, bats can be exposed to both chronic and acute poisoning which can result in death. At lower levels, chronic poisoning may raise a bat's metabolism, burning the limited fat resources more quickly and possibly causing them to starve to death. In addition, broad spectrum insecticides can deplete insect diversity and limit the food sources available for bats.

**Assessment Narrative:**

Hoary bats are the largest bats of northeastern North America. They are ranked as S3 (uncommon).

Only five occurrences found in Vermont in the past 10 years. A specimen was netted in Addison County in 2002 (Decker & Kilpatrick 2002) and a hoary bat was detected by Anabat Bat Detector along the Lamoile River near Fairfax (Kilpatrick pers comm). The population has declined significantly since 1900. In 2001, one post reproductive female and one juvenile female hoary bat were captured by Environmental Solutions and Innovations during mist netting (ESI, 2001). The most recent report in Vermont was in 2003. Mist netting in the N. Springfield Lake/Stoughton Pond area yielded 45 bats the first sampling period and 53 bats in the second sampling period (Chenger 2003). One male hoary bat was captured as a result of the survey. In Connecticut 300 hours of mist netting yielded one hoary bat. Due to their solitary nature, we know the least about the 3 tree bat species in Vermont (red, hoary, and silver-haired).

### Bibliography:

Common Name: New England Cottontail  
Scientific Name: Sylvilagus transitionalis  
Species Group: Mammal

**Conservation Assessment:**

- **Final Assessment:** High Priority
- **Global Rank:** G4
- **State Rank:** SU
- **Global Trend:**
- **State Trend:** Unknown
- **Extirpated in VT?** no
- **Regionally Rare?** yes

**Assessment Narrative:**

The New England cottontail is rare, possibly extirpated in Vermont.

S. transitionalis was abundant in Vermont in the 1940s. They were last documented in 1946. Widespread introductions of S. floridanus and habitat changes have resulted in apparent competition and possibly hybridization with eastern cottontails. Despite concerted trapping efforts in Vermont no evidence of S. transitionalis has been found since 1991.

**Distribution Summary:**

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge ☑
- Extensive Local Knowledge ☐
- Regional Literature ☑
- General Literature ☑

New England cottontails are associated with many types of vegetation but are most often found in early successional old fields, 10-25 years post-disturbance with high stem density (9000-10,000 stems/hectare). It is critical that patches of dense hardwood and softwood shrubs, seedlings and saplings at least .5 meters tall and less than 7.5 meters in diameter be closely spaced to facilitate usage. Connectivity between patches is also important. Isolated patches are much less frequently used (Tumosa 2001). New England cottontails seldom venture far from dense cover and in winter will inhabit larger patches (greater than 10 ha) (DeGraff and Yamasaki, 2001). They cannot colonize areas already inhabitant by Eastern cottontail. Home ranges can be linear along riparian areas, road sides etc.

10-25 yrs. Post disturbance
Common Name: New England Cottontail

**Vegetation Categories Used:**
(see Appendix B for habitat, community & landscape organization and conservation summaries)
- Early Succession Boreal Hardwoods
- Early Succession Pine and Hemlock
- Grasslands and Hedgerows

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Habitat Succession
- Invasion by Exotic Species

**Description of habitat problem(s):** Fragmentation and isolation of patches results in lower survival rates and skewed sex ratios and increases vulnerability to extirpation due to chance events (natureserve.org). Habitat patches less than 3 acres in size increases the risk of predation. Decline in patch size (less than 15-75 ha) and increase in juxtaposition (greater than 500m) reduces survivability of New England cottontails. Loss of 10-25 year post-disturbance habitat due to conversion, succession and fragmentation also negatively influences N.E. cottontail recovery. Competition from eastern cottontail is also a problem. The eastern cottontail will occupy a habitat first and exclude NE Cottontail

**Non-Habitat Problems:**
- Competition

**Description of non-habitat problem(s):** Competition with eastern cottontail

Assessment Narrative:

Ranked as S2 in Vermont and considered a species of special concern.

Talus slopes are the species' refugial habitat. In some locations may be found in some early successional forest habitat (Kirkland 1977; Martell and Radvanyi 1977) (disappears 7 years after disturbance) and krumholtz. We don't know why the population fluctuates so much and there are relatively few known populations. There have been several historic records: 1937-1940: 20 specimens in Island Pond at 1400' elevation; 1953: 2 specimens in Brighton on the talus slopes of NW Bluff Mountain; 1954: one specimen near Smugglers cave on Mt. Mansfield; 1958-1959: 4 specimens from Nebraska Notch, Mt. Mansfield; 1966: 2 specimens (one male and one female collected in Nebraska Notch, Mt Mansfield State Forest at 1900 ft in Underhill; (Everett Marshall pers., com, Vt. Natural Heritage database). Current sites include: Whenlock WMA (Chipman, 1994); West Mountain WMA (Kilpatrick, 2001); East Mountain, East Haven (Kilpatrick, 2005), Eat Charleston (Kilpatrick, pers., com).

Distribution Summary:

Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Occurs in disjunct populations that are not genetically differentiated so movement corridors may be important. This species is very habitat selective. They use moist talus habitats among mossy rocks and logs in spruce/ fir and northern hardwood forests, cedar swamps, and krumholtz. May be naturally rare due to habitat...
species. Rock vole has been reported in three-five year old clearcuts with slash however, not in Vermont. Critical habitat includes cool, moist talus and mossy rocks usually a stream or other surface water in the immediate vicinity.

</tbody>
</table>

**Vegetation Categories Used:**

- Cliffs and Talus
- Softwood Swamps
- Spruce Fir Northern Hardwood

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

**Description of habitat problem(s):** Mesic aspect of habitat is important so the loss of forest cover may dry out the site. Loss of connectivity may be a problem. Habitat is isolated and local populations may go extinct. Repopulation may require habitat corridors of coniferous forests that connect optimal habitats. Activities that destroy or degrade talus habitat would impact rock vole populations.

**Non-Habitat Problems:**

**Description of non-habitat problem(s):** Competition from meadow mouse as a result of habitat conversion, particularly near talus areas, could limit the rock vole. Metapopulation structure is not clearly understood but local populations appear to go extinct and then are repopulated. In Massachusetts and West Virginia populations were negatively affected by high levels of deer over the long term (Healey and Brooks 1988).

**Assessment Narrative:**

status: Appears to be stable.

Often a pest that appears to do well in agricultural settings. However little is known about this species outside this setting or in its native habitat. Fewer than 50 specimens collected in the state. Known from very few localities including the flanks of Ide Mountain, West Lyndon Center (Miller, 1964); Island Pond (Miller, 1964); Sherburne (Osgood, 1936); and from Colchester and Duxbury (Kilpatrick, pers. com). Although often reported as an agricultural pest, especially in apple orchards, much of the reported damage is the result of meadow voles (Microtus pennsylvanicus). Woodland voles are only known to occur in orchards in Putney, Mendon, and Bennigton (Kilpatrick, 1979).

#### Distribution Summary:

### Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge  
- Extensive Local Knowledge  
- Regional Literature  
- General Literature

Defining habitat characteristic is well-drained sandy loam soils. Found in all places with these soils (e.g. agricultural fields and older forests). Favors well-drained upland forests, grasslands, meadows, or orchards but can be found in marshes and swamps (DeGraff and Yamasaki, 2001). May require a ground cover of leaves or duff or grass. Forages primarily below ground digging tunnel systems 3 inches to 12 inches below ground. Nests are found under dead and down material, rocks, or in burrows. They are active throughout the year and eat tubers, roots and bulbs, seeds, nuts fruits, bark and leaves (DeGraff and Yamasaki, 2001). Can be a

Uses a variety of habitats from marshes and open meadows to moist deciduous and mixed forest. Common in orchards in Southern Appalachia but seems to prefer moist mixed deciduous forest with moist substrata such as sphagnum bog or a thick loose duff layer. Found in wet grasslands and hemlock/pine forest. Utilizes the burrow systems of hairy-tailed moles. The s. bog lemming will use clearcuts and other small forest openings with adequate ground cover (kirkland 1977b, in DeGraff 2001).

**Assessment Narrative:**

Believed to be extirpated in Vermont and the rest of New England. Based on bounty records, wolves were historically common in Vermont but were eliminated from the state by the mid to late 1800’s as the result of a $20.00 bounty and habitat changes.

The wolf is currently considered extirpated in the Northeast but a regional population exists in Canada with potential for migrants to arrive in Vermont within next 20 years (although the St. Lawrence river and adjacent agricultural/urban/suburban environments may pose a substantial barrier). However, habitat across the taxon's historic range has been reduced in quantity and quality and a majority of the historic populations have been extirpated. Recovery/reintroduction efforts are complicated by taxonomic uncertainty about the wolf or wolves that historically occupied the region, by public attitudes towards wolves, and by the potential interaction with the eastern coyote.

  - **Outside US** □

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge □  
- Extensive Local Knowledge □  
- Regional Literature □  
- General Literature □

Prefers core forest areas with limited human access, road densities of <1mi road per 1square mile of habitat. Prefers areas with <8 people per square kilometer (<3 mi2). Requires adequate amount of prey base (deer, moose, beaver). Estimates by Mladenoff and Sickley (1998) and Harrison and Chapin (1998) suggested that 20,000 mi2 to 25,000 mi2 of habitat remains in northern New England. Of that, Harrison and Chapin (1998)
suggest that only 950 mi² is in Vermont. They based their estimates on road densities, human densities, and available forested habitat. Mladenoff and Sickley suggested that 20,000 mi² of habitat could support 700 to 1439 wolves. Optimum habitat for the wolf depends in large part on the availability of prey (deer, moose, beaver) in predominantly forested areas with low human densities. In areas of high prey densities wolves may consume 1 deer/wolf/18-45 days (Mech 1974 in Tumosa 2003).

Regional corridors and habitat linkages are critical to maintaining wolves in potentially fragmented landscapes. Three key elements to wolf population and viability are large relatively undeveloped blocks of habitat, adequate prey, and freedom from excessive human exploitation (Fritts and Carbyn 1995; Fuller 1997; Haight et al. 1998 in Parson 2003).

undisturbed den sites

**General Habitat Preferences:**

- Minimum Elevation (m): 0
- Maximum Elevation (m): 0
- Patch Size Requirements: > 1000 ha
- Prefers large wetland complexes:
- Prefers large expanses of grassland habitat:

- Prefers actively managed woodland:
- Requires movement corridors: ✓
- Prefers large expanses of forest habitat: ✓

**Vegetation Categories Used:**

- Floodplain Forests
- Northern Hardwood
- Oak-Pine Northern Hardwood
- Spruce Fir Northern Hardwood

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Impacts of Roads or Trails

**Description of habitat problem(s):** Human activity associated with roads, vehicles, and houses seem to negatively influence use of an area by wolves. Conversion of forest habitat to non forest (development and agriculture) also negatively affects wolf densities. Wolves cannot survive without adequate prey, adequate protection, and adequate public support (Theberge et al, 1996 in Tumosa 2003). Connectivity with other wolf packs in the region is important to recovery of wolves in the northeast. Potential core habitat in southern Vermont is fragmented from core habitat in northeastern Vermont.

**Non-Habitat Problems:**
- Competition
- Genetics
- Loss of Prey Base
- Trampling or Direct Impacts

**Description of non-habitat problem(s):** Competition/hybridization with eastern coyote may impact the
Common Name: Wolf  
Scientific Name: Canis sp?  
Species Group: Mammal

success of wolf recovery. A better understanding of the ecological role of the eastern coyote is necessary. It could be argued that the eastern coyote is now the dominant, large canid predator in the Northeast. It is not clear how the existing coyote population would respond to the establishment of a wolf population and vice versa. In addition, recovery of wolves in the northeast would not be successful without public support. Any recovery effort would have to be preceded by a public input process that evaluated public attitudes. Mech (1995 in Parsons 2003) suggests that increased human tolerance has led to wolves occupying areas of higher road densities in Minnesota. Inadequate levels of prey would significantly affect wolf densities and survivability.

**Conservation Assessment:**

- **Final Assessment**: Medium Priority
- **Global Rank**: G5  
- **Global Trend**: Stable  
- **State Rank**: S5  
- **State Trend**: Stable  
- **Extirpated in VT?**: No  
- **Regionally Rare?**: No

**Assessment Narrative:**

Currently, the black bear population is stable and found throughout Vermont. Certain habitat types are critical to the sustainability of Vermont's black bear population.

Critical habitat (including mast stands, forested wetlands, and travel corridors) could be vulnerable due to habitat loss and conversion from development and fragmentation. Black bear depends on large expanses of forested blocks with connectivity that could be lost due to development and fragmentation. It is already possible that Vermont has two distinct genetic populations due to fragmentation with the southern population below critical levels.

**Distribution:**

**Natural History Elements:**

- **Home Range**: > 1000 ha

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Conversion of Habitat
- Habitat Fragmentation
- Impacts of Roads or Trails

Description of habitat problem(s): Food is the most important resource for black bears. Nuts of American beech trees are an important primary fall food source in Northern New England. Nutritional plane of female bears and their reproductive rates would decline substantially if American beech trees diminish significantly in the forests of Vermont. Forest management practices, disease events and weather events may affect stands of mast producing trees.

Comprehensive Wildlife Conservation Strategy
Species Assessment Report

Common Name: American Marten
Scientific Name: Martes americana
Species Group: Mammal

Conservation Assessment:

Final Assessment: High Priority
Global Rank: G5
State Rank: S1?

Extirpated in VT? Unknown
Regionally Rare? No

Assessment Narrative:
The marten is presently listed as endangered in Vermont. Prior to European settlement, the species ranged from the Canadian border to Massachusetts and according to Thompson (1853) was very plentiful throughout most of the state. Marten populations declined in the late 1800's due to widespread habitat conversion and over harvest. Records since the turn of the century are scarce (DiStefano et al. 1990). The most recent documentation is from Hogback Mountain, Windham County in 1954. (Trombulak and Royar, 2000). A reintroduction effort was initiated by the U.S. Forest Service and the Vermont Fish and Wildlife Department in 1989, 1990, and 1991 in the southern portion of the Green Mountain National Forest (Wallingford, Stratton). One hundred and fifteen marten were released into Vermont, 11 from New York and 104 from Maine (K.Royar, pers com). The reintroduction effort appears to have been unsuccessful. Recently, animals and sign have been documented in the Northeast Kingdom (W.Staats, pers com).

Marten are presently extirpated or exist at very low levels in Vermont. They require deep fluffy snow and broad expanses of mature coniferous forest. They are likely to be impacted by global warming. Competition from fisher may also influence distribution.

Distribution:

Natural History Elements:

Home Range: > 1000 ha
Migrant? No

Within watershed
Within biophysical region
Within VT
Within Region
Within US
Outside US

Distribution Summary:
American Marten  

**Species Assessment Report**

**Common Name:** American Marten  
**Scientific Name:** Martes americana  
**Species Group:** Mammal

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Marten require large, unfragmented forests with sufficient dead and down wood to support rodent populations as a prey base and to allow marten to hunt below snow level (Bissonette et al., 1997). For every 9 square km of marten habitat, no more than 25% of the forest should be open. Deep fluffy snow is needed to out compete fisher. According to Chapin et al (1996), marten require late successional forests and select habitat at a landscape level scale. In addition, researchers documented that "forest fragmentation influenced spatial use of habitat by marten in an extensively clearcut industrial forest landscape" (Chapin et al., 1996) In managed landscapes efforts need to be made to maintain large blocks of intact late successional forest habitat. In this same study, female marten tolerated 20% of their home range in regenerating forest.

**General Habitat Preferences:**

- Minimum Elevation (m): 300
- Maximum Elevation (m): 1400
- Patch Size Requirements: > 1000 ha
- Prefers large wetland complexes: □
- Prefers large expanses of grassland habitat: □
- Prefers habitat mosaics: □
- Prefers developed landscapes: □
- Prefers actively managed woodland: □
- Requires movement corridors: □
- Prefers large expanses of forest habitat: □

**Vegetation Categories Used:**

(see Appendix B for habitat, community & landscape organization and conservation summaries)

- Northern Hardwood
- Softwood Swamps
- Spruce Fir Northern Hardwood

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Climate Change
- Conversion of Habitat
- Habitat Fragmentation

**Description of habitat problem(s):** Conversion of habitat and fragmentation could be a problem to marten. Optimum habitat must be at least 75% late successional forest. Some current silvicultural practices could reduce appropriate vertical and horizontal structure necessary for marten survival. Climate changes that result in a warming trend could also reduce the potential for marten survival in Vermont. Warmer winters that result in less snow may promote fisher populations in areas that historically were limited to marten due to deep snow.

**Non-Habitat Problems:**

- Competition
- Predation or Herbivory

**Description of non-habitat problem(s):** It has been speculated that higher fisher densities may limit marten populations (Krohn,1995). Fisher pelt prices and corresponding trapper effort dropped drastically in the late
Vermont Department of Fish and Wildlife

1980's. Since then the fisher population has increased and expanded its range. Competition with, and predation by, fisher could negatively influence marten success in Vermont.

Species Assessment Report

Common Name: Long-tailed Weasel
Scientific Name: Mustela frenata
Species Group: Mammal

**Conservation Assessment:**

| Final Assessment: Medium Priority | Global Rank: G5 | Global Trend: unknown
| State Rank: S3S4 | Exirpated in VT? no |

**Assessment Narrative:**

Assumed to be common in Vermont but status is not monitored and little is known about abundance and distribution.

**Distribution:**

**Natural History Elements:**

- Home Range: < 100 ha
- Migrant? No
- Within watershed
- Within biophysical region
- Within VT
- Within Region
- Within US
- Outside US

**Distribution Summary:**

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

The long-tailed weasel inhabits the broadest range of any of the weasels from low elevations to above treeline across the continent (Novak et al, 1987). They occupy a variety of habitats from forest and shrubs adjacent to stone walls to fields, wetlands and standing water. Where it overlaps with the short-tailed weasel, it may occupy more open habitats while the short-tailed weasel is more common in forested or wetland areas. Areas with high prey density are important. The long-tailed weasel feeds on small mammals such as mice, rabbits, voles and ground nesting birds. Water seems to be a critical factor. Hamilton (1933) reported that they can drink 25cc of water per day and therefore, it may be restricted to habitats in close proximity to standing water. The long-tailed weasel is more of a food generalist than the short-tailed weasel. On the average, long-tailed weasels will take 1.5 voles per day (Powell 1973 in Wild Furbearer Mgt 1987). The weasel uses excavated burrows or holes and/or crevices for den sites (DeGraff and Yamasaki, 2001).
Common Name: Long-tailed Weasel  
Scientific Name: Mustela frenata  
Species Group: Mammal

</table>

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
Conversion of Habitat
Habitat Alteration
Habitat Succession

Description of habitat problem(s): problems are not well understood but conversion of habitat/habitat succession/habitat degradation could negatively affect weasel populations.

Non-Habitat Problems:
Predation or Herbivory

Description of non-habitat problem(s): Predation: cats and dogs, foxes, raptors and rattlesnakes
Proximity to humans: Increased predator control and potential for road kill may be a problem. Weasels could be affected directly and indirectly by pesticide use (effects on reproduction, habitat, and/or food supply).

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Requires a dependable source of food. Den sites include muskrat bank burrows, beaver dens, within 30 meters of water. Mink are adaptable to many different wetland habitats including beaver created wetlands, lakes, streams and ponds. Intact vegetation along the perimeter of streams, lakes and wetlands is an important habitat feature of otter habitat. Beaver bank dens and lodges are also used by mink. Beaver created wetlands provide critical foraging and denning habitat. Logjams resulting from fallen trees also provide shelter and foraging habitat. Mink also require clean water and an adequate prey base.
**Common Name:** Mink  
**Scientific Name:** Mustela vison  
**Species Group:** Mammal

**Assessment Narrative:**
The otter population in Vermont is stable and distributed throughout the state.

The river otters "piscivorous diet and high trophic position make it a noteworthy indicator of pollution in aquatic systems" (Melquist and Dronkert 1987). Prey may also be susceptible to pollution and acid rain. Of 20 otter tested in 2001 for mercury in Vermont, two had levels higher than that recommended by the EPA (K.Royar, pers. com).

**Distribution:**

The otter population is stable and distributed throughout the state. Otter are harvested in every watershed in Vermont.

Prefer large wetland complexes: ☑
Prefer large expanses of grassland habitat: ☐
Prefer habitat mosaics: ☐
Prefer developed landscapes: ☐
Prefer actively managed woodland: ☐
Requires movement corridors: ☑
Prefer large expanses of forest habitat: ☐

Vegetation Categories Used:
(see Appendix B for habitat, community & landscape organization and conservation summaries)

Aquatic: Fluvial
Aquatic: Lake Champlain
Aquatic: Large Lake Champlain Tribs Below Falls
Aquatic: Lower CT River

Current Problems:  (see Appendix C for definitions of problem categories)

Habitat Problems:
Habitat Alteration

Description of habitat problem(s): Forested riparian buffers are key components of otter habitat. Loss and/or degradation could influence otter habitat selection and productivity. Historically, otter were limited by human encroachment, habitat destruction, and unregulated harvest. In Vermont, the extirpation of beaver, loss of habitat, and pollution resulted in a much reduced population throughout the 1800's and early 1900's. Otter populations have rebounded with the return of the beaver but increasing development pressure...
and pollutants such as mercury could negatively affect future population levels.

**Non-Habitat Problems:**

Loss of Prey Base

Pollution

*Description of non-habitat problem(s):* Contaminants such as PCB's, mercury, and other heavy metals can buildup in the tissue of otter and negatively affect reproduction and survival.

State Rank: SNA  
State Trend: Na  
Extirpated in VT? yes  
Regionally Rare? no

**Assessment Narrative:**

Presently listed as endangered in Vermont. Regionally, the only known viable population exists in northern Maine. Lynx are believed to be extirpated from New Hampshire, Vermont, and New York. Vermont is at the southern edge of lynx range. Only 5 historical records exist in Vermont: a museum specimen in Royalton, Vermont; an animal killed in Windham, Vermont in 1928 (Osgood, 1938); an animal taken in Ripton, Vermont in 1937 (Hamilton and Whittaker, 1979); and a lynx trapped in St. Albans, Vermont in 1968 (J. Hall, pers. Com.). In the late 1700's a bounty was paid on a lynx taken in Calais, Vermont (Vermont State Archives). There was a credible sighting in the Northeast Highlands (Yellow Bogs) in 2003 (K. Royar, pers. com).

Recovery of lynx is limited by global climate change and potential for hybridization with bobcats. The influence of competition from coyote, fisher, and bobcat, which could potentially be exacerbated by global climate change, is not clearly understood (Ray et. al. 2002). In addition, maintaining connectivity between Vermont habitats and habitats in Canada, New Hampshire, and Maine is critical for the recovery of a resident population in Vermont.

At least 70 kittens have been produced by the northern Maine population in the last eight years. The areas to which they disperse is unclear.

**Distribution:**

  - Home Range: > 1000 ha
  - Migrant? No
  - Within watershed □
  - Within biophysical region □
  - Within VT □
  - Within Region □
  - Within US □
  - Outside US □

**Distribution Summary:**

- Killed in Windham 1928
- Killed in St Albans 1968
- Killed in Calais 1797
- Sighting in Yellow Bogs 2003
- Addision County 1937
Lynx are generally found in softwood and/or mixed forests in regions with deep snow. They prefer complexes of regenerating forest where snowshoe hare are likely to be abundant (Hoving 2001) such as areas of dense softwood in association with openings of 2-4 hectares (Novak 1987). Fuller (1999) and Homyack found that hare densities in Maine responded to habitat change in a logarithmic rather than a linear fashion: 12-15 year old regenerating clear-cuts had 280 times higher hare densities than early regenerating partially harvested stands (1.6/ha vs..01/ha); mature mixed forest stands had about seven times higher snowshoe hare densities than those that were partially harvested (Ray et.al. 2002). Critical habitat needs include snow depths greater than 268cm or 2.6 meters. Lynx are associated with areas with less than 27% deciduous forest (Hoving, 2001). Preliminary analysis suggests lynx denning requirements include volumes of downed woody debris equivalent to what has been found in 100 year old stands. In a Maine study equivalent attributes were found in 15 year old stands probably due to a spruce budworm outbreak in the 1970's. In addition, stem density was high and horizontal cover thick (Ray et.al. 2002).

**Vegetation Categories Used:**

- Early Succession Boreal Conifers
- Early Succession Spruce-Fir
- Spruce Fir Northern Hardwood

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Climate Change
- Habitat Fragmentation
- Habitat Succession
- Impacts of Roads or Trails

**Description of habitat problem(s):** Lynx could be limited by road densities, prey densities, climate factors (<268 cm snow) and lack of softwood (Hoving 2001). Past land use practices and poorly planned turn-of-the-century (19th) logging have resulted in a 75% loss of spruce-fir habitat on the Green Mountain National Forest (Ruediger et al, 2000). In addition, fragmentation of habitat corridors between Canada, New Hampshire, and Maine may limit lynx dispersal to Vermont. Hoving (2001) suggests that snow depth can determine the distribution of lynx vs. bobcat. Climate change could influence future weather patterns/snowfall and therefore affect future distribution of lynx in the northeast.

### Conservation Assessment:

**Final Assessment:** Medium Priority  
**Global Rank:** G5  
**Global Trend:**  
**State Rank:** S4  
**State Trend:** Unknown  
**Exirpated in VT?** no  
**Regionally Rare?** no

**Assessment Narrative:**

Apparently common and well distributed throughout Vermont although higher densities appear to exist in the Champlain Valley and the Taconics possibly due to higher prey densities and lower fisher densities. Population has declined since the middle of the 20th century due to land use changes that affect prey densities as well as competition from fisher and coyotes.

Critical habitat needs are unknown in Vermont. It is believed that bobcats depend on connected expanses of undeveloped habitat. The dynamics between bobcat, coyotes, fisher and landscape change are not clearly understood. Bobcats were bountied until 1971. Between 1955 and 1970 an average of 265 bobcats were taken per year as a result of the bounty (K. Royar, pers.com). It is believed that bobcat populations have declined since then primarily as a result of competition from coyotes and fisher and a decline in prey species as a result of habitat changes.

### Distribution:

**Natural History Elements:**

- **Outside US**

**Distribution Summary:**

### Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge  
- Extensive Local Knowledge  
- Regional Literature  
- General Literature

Bobcats use a variety of habitat types including mixed woodlands, wetlands, agricultural/forest edges, and areas of dense undergrowth supporting high densities of prey species such as snowshoe hare, rabbits, and other small mammals and birds. Deer wintering areas may be important in winter for cover and as a source of prey (deer). Bobcats seem to be most successful in large tracts of undeveloped lands connected by vegetated...
Bobcat

Scientific Name: Lynx rufus
Species Group: Mammal

linkages. In Vermont, steep, rocky cliffs may be important as winter refugia and breeding habitat.

</table>

**Vegetation Categories Used:**

- Northern Hardwood

(see Appendix B for habitat, community & landscape organization and conservation summaries)

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Habitat Succession

*Description of habitat problem(s):* It is believed that bobcats in Vermont may require rocky ledges as winter and denning habitat. Direct loss of these areas, as well as, habitat fragmentation and conversion (to development) in habitats adjacent to these ledges, could affect bobcat survival. Disturbance from humans may influence habitat selection (McCord, 1974). Prey availability also affects bobcat distribution and survival.

**Non-Habitat Problems:**
- Competition
- Loss of Prey Base

*Description of non-habitat problem(s):* Bobcat numbers have declined since coyotes have become established in Vermont. Prey species have declined in some areas due to loss of early successional habitat.

Distribution Summary:

Habitat Description:
Habitat Information is based on the following:
Limited Local Knowledge☑ Extensive Local Knowledge □ Regional Literature □ General Literature □

Cougars require remote, undisturbed, and un-fragmented habitat on a large scale and an adequate prey base to survive. Beier (1993), using simulated population dynamics, estimated that an area of 1,000 to 2,200 square kilometers (372 to 818 square miles, depending on the demographics of a particular population) was needed for a population of 15-20 adult cougars to have a very low risk (<98%) of extinction within 100 years. Smaller areas might suffice where adequate dispersal corridors allow movement among populations. Cougars typically avoid open areas and areas of human population (Kitchell 1999), often following watercourses in open areas to remain concealed by bank-side vegetation (Russell 1978). Specific dispersal barriers include roads and nighttime illumination (Beier 1993, 1995). Cougars are limited to areas with ungulate-size prey. Deer/Elk wintering habitat is seasonally favored. (Lindzey 1987).

**Vegetation Categories Used:**
- Cliffs and Talus
- Northern Hardwood
- Spruce Fir Northern Hardwood

(see Appendix B for habitat, community & landscape organization and conservation summaries)

**Current Problems:**  (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Fragmentation
- Impacts of Roads or Trails

*Description of habitat problem(s):* Where they still exist, mountain lions presumably require access to large expanses of remote, rugged, forested terrain. Human development/disturbance and prey availability affects mountain lion distribution and survival.

**Non-Habitat Problems:**
- Loss of Prey Base
- Trampling or Direct Impacts

*Description of non-habitat problem(s):* Negative human attitudes towards mountain lions in regards to human safety and perceived impacts on deer populations limits successful establishment/ maintenance of lion populations in the East.

**Species Assessment Report**

**Species:** Jefferson Salamander  
**Scientific Name:** Ambystoma jeffersonianum  
**Species Group:** Herp

### Conservation Assessment:

**Final Assessment:** High Priority  
**Global Rank:** G4  
**State Rank:** S2  
**Global Trend:** Unknown  
**State Trend:** Unknown  
**Exirpated in VT?** No  
**Regionally Rare?** Yes

**Assessment Narrative:**

Jefferson Salamander is rare in Vermont (S2, SC), and is considered a species of conservation concern within the region due to evidence of population declines, and the fact that a high proportion of the global population occurs within the Northeast (Terres 1999).

Jefferson Salander breeding habitat is limited almost exclusively to temporary woodland pools surrounded by relatively large stands of mature hardwoods. There is evidence that the species may be sensitive to forest fragmentation, and in southern New England some populations appear to have been outcompeted by its congener, the Blue-spotted Salamander (Klemens, personal communication). In addition, unisexual female hybrid populations exist that introduce uncertainties about the species’ taxonomy, population biology, persistence, and long-term viability.

### Distribution:

**Biophysical Regions in Vermont**

**Known Watersheds**
- CT-Bellows Falls Dam to Vernon Dam
- CT-Waits River to White River
- CT-White River to Bellows Falls
- Hudson-Hoosic Rivers
- Otter Creek
- White River

**Possible Watersheds**

- **Within VT**
- **Within Region**
- **Within US**
- **Outside US**

**Distribution Summary:**

The distribution of this rare woodland species is widespread but scattered in Vermont.
Common Name: Jefferson Salamander
Scientific Name: Ambystoma jeffersonianum
Species Group: Herp

Winooski River

**Habitat Description:**

Habitat Information is based on the following:

Limited Local Knowledge ✓  Extensive Local Knowledge □  Regional Literature ✓  General Literature ✓

Requires well-shaded, relatively mature hardwood/hemlock forest stands with abundant course woody debris, leaf litter, and underground refugia (small mammal tunnels, rock crevices, etc) surrounding temporary woodland (vernal) pools (Faccio 2003). May also use semi-permanent pools. Most commonly found in ridgetop, mid-elevation Northern Hardwood forests in the foothills of the Green Mountains.

**Vegetation Categories Used:**

Aquatic: Man-Made Water Bodies
Northern Hardwood
Seeps and Pools
Spruce Fir Northern Hardwood

(see Appendix B for habitat, community & landscape organization and conservation summaries)

**Current Problems:**  (see Appendix C for definitions of problem categories)

**Habitat Problems:**

Climate Change
Habitat Alteration
Habitat Fragmentation
Impacts of Roads or Trails
Sedimentation

*Description of habitat problem(s):* Any habitat conversion, alteration, or fragmentation that disrupts species’ ability to move between breeding and terrestrial sites, changes water/soil chemistry, temperature, pool hydroperiod, humidity, etc, may have negative effects. Road mortality can have major impacts on migrating adults and dispersing juveniles, especially when located between terrestrial and breeding habitats. Climate change that affects hydroperiod and/or water temperature of breeding pools could have significant impacts on productivity (Rowe and Dunson 1995).

**Non-Habitat Problems:**

Competition
Genetics
Pollution
Jefferson Salamander

Common Name: Jefferson Salamander
Scientific Name: Ambystoma jeffersonianum
Species Group: Herp

Trampling or Direct Impacts

Description of non-habitat problem(s): Unisexual, female hybrid populations reproduce via gynogenesis (requires sperm from diploid males which is not incorporated into the genome of embryos; Petranka 1998), resulting in female-biased sex ratios. Since hybrid females require males in the population for successful breeding, but do not produce males to replace those that have been lost, they may have the potential to dilute genetic variability of diploid populations. Competition from the Blue-spotted Salamander, which is more tolerant of disturbed habitats (Klemens 1993), may be a problem in areas where both species are found together (Champlain Valley?, southern NE). Loss of metapopulation structure due to fragmentation of suitable habitats by roads or other non-permeable development is problematic. Jefferson Salamander is more sensitive to acidification of breeding pools compared to other Ambystoma species (Petranka 1998). Complete egg mortality occurs in pools with low pH, and water with a pH <4.5 if often lethal to larvae. Also, widespread treatment of breeding pools to control West Nile Virus would likely have negative effects on amphibians. Long-lived amphibian with relatively fewer eggs that may not breed every year.

<th>Number of utilized pools</th>
<th>VTrans, municipalities</th>
<th>VTrans, development conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>If loss of important sites is likely due to development, consider creating or enhancing other pools that might allow some adults to transfer to the new site if they encounter it or develop a new breeding population from dispersal of colonizers.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Standards

- Maintain habitat mosaic and maintain connectivity between breeding pools. If two large sites are separated beyond the dispersal distance of a species it might be helpful to create or enhance pools that would link the two large sites.

- Number of pools within habitat matrix: Landowners, consulting foresters, State Lands management fund, WHIP, LIP, Current Use

#### Compatible Resource Use

- Site all permanent roads more than 200 meters from a breeding pool, downslope of the pool if possible.

- Number of roads sited to minimize impacts to pools: VTrans, developers, VTrans, development conditions
**Common Name:** Jefferson Salamander  
**Scientific Name:** Ambystoma jeffersonianum  
**Species Group:** Herp

**Bibliography:**

Klemens, M.K. 1993. Amphibians and reptiles of Connecticut and adjacent regions. State Geological and Natural History Survey of Connecticut, Bulletin No. 112 318 pp. (Unfortunately this is currently out of print.)

**Common Name:** Jefferson Salamander  
**Scientific Name:** Ambystoma jeffersonianum  
**Species Group:** Herp

Blue-spotted Salamander is rare in Vermont (S3, SC), and is considered a species of conservation concern within the region due to its unknown population status, and taxonomic uncertainty (Terres 1999).

The blue-spotted salamander is dependent on habitat mosaics consisting of lowland forest adjacent to wetlands suitable for breeding. In addition, unisexual female hybrid populations exist that introduce uncertainties about the species’ taxonomy, population biology, persistence, and long-term viability.

**Distribution:**

Blue-spotted Salamander is rare in Vermont (S3, SC), and is considered a species of conservation concern within the region due to its unknown population status, and taxonomic uncertainty (Terres 1999).

The blue-spotted salamander is dependent on habitat mosaics consisting of lowland forest adjacent to wetlands suitable for breeding. In addition, unisexual female hybrid populations exist that introduce uncertainties about the species’ taxonomy, population biology, persistence, and long-term viability.

**Known Watersheds**

- CT-Johns River to Waits River
- CT-Waits River to White River
- CT-White River to Bellows Falls
- Deerfield. MA-VT
- Passumpsic Vermont
- White River
Common Name: Blue-spotted Salamander  
Scientific Name: Ambystoma laterale  
Species Group: Herp

Winooski River

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge  
- Extensive Local Knowledge  
- Regional Literature  
- General Literature

Requires hardwood/mixed forest stands with abundant course woody debris, leaf litter, and underground refugia (small mammal tunnels, rock crevices, etc) surrounding a variety of wetland types, including red maple swamps, fens, marshes, temporary woodland (vernal) pools, etc. Most commonly found in bottomland forests adjacent to wetland with sufficient cover for breeding. More tolerant of disturbed habitats than Jefferson Salamander (Klemens 1993).

**General Habitat Preferences:**

- Minimum Elevation (m): 30  
- Maximum Elevation (m): 350  
- Patch Size Requirements: > 10 ha  
- Prefers large wetland complexes: ☑  
- Prefers large expanses of grassland habitat: ☐  
- Prefers habitat mosaics: ☑  
- Prefers developed landscapes: ☐  
- Prefers actively managed woodland: ☐  
- Requires movement corridors: ☑  
- Prefers large expanses of forest habitat: ☐

**Vegetation Categories Used:**

(see Appendix B for habitat, community & landscape organization and conservation summaries)

- Aquatic: Man-Made Water Bodies  
- Hardwood Swamps  
- Marshes and Sedge Meadows  
- Northern Hardwood  
- Oak-Pine Northern Hardwood  
- Open Peatlands  
- Seeps and Pools  
- Shrub Swamps  
- Softwood Swamps  
- Spruce Fir Northern Hardwood

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Climate Change  
- Conversion of Habitat  
- Habitat Alteration  
- Habitat Fragmentation  
- Impacts of Roads or Trails

**Description of habitat problem(s):** Any habitat conversion, alteration, or fragmentation that disrupts species’ ability to move between breeding and terrestrial sites, changes water/soil chemistry, temperature, pool hydroperiod, humidity, etc. may have negative effects. Road mortality can have major impacts on migrating adults and dispersing juveniles, especially when located between terrestrial and breeding habitats. Climate change that affects hydroperiod and/or water temperature of breeding pools could have significant impacts on productivity (Rowe and Dunson 1995).

**Non-Habitat Problems:**
Vermont Department of Fish and Wildlife
Comprehensive Wildlife Conservation Strategy
Species Assessment Report

Common Name: Blue-spotted Salamander
Scientific Name: Ambystoma laterale
Species Group: Herp

Description of non-habitat problem(s):
Unisexual, female hybrid populations reproduce via gynogenesis (requires sperm from diploid males which is not incorporated into the genome of embryos; Petranka 1998), resulting in female-biased sex ratios. Since hybrid females require males in the population for successful breeding, but do not produce males to replace those that have been lost, they may have the potential to dilute genetic variability of diploid populations. Loss of metapopulation structure leading to genetic isolation due to fragmentation of suitable habitats by roads or other non-permeable development is problematic. Problems from acid precipitation that lowers pH of breeding pools may reduce productivity. Also, widespread treatment of breeding pools to control West Nile Virus would likely have negative effects on amphibians. Long-lived amphibian with relatively fewer eggs that may not breed every year.

**Global Rank:** G5  
**State Rank:** S5  
**Global Trend:**  
**State Trend:**  
**Exirpated in VT?** No  
**Regionally Rare?** No

**Assessment Narrative:**  
Spotted salamander is found in pools adjacent to woodlands. It is widespread and abundant, but is killed in large numbers when it migrates across roads to and from it breeding pools, and is therefore a SGCN.

Conservation status could change over time with increased human pressure that impacts the species in Vermont. For now we consider it to be a medium priority species.

Species: Spotted Salamander (Ambystoma maculatum)

Description of habitat problem(s): Habitat problems for the Spotted Salamander include loss of upland or pool habitat, loss of movement between habitats, road mortality, if climate change results in less water.

Non-Habitat Problems:

Reproductive Traits

Trampling or Direct Impacts

Description of non-habitat problem(s): Loss of connectivity to other populations and road mortality, driving vehicles through breeding pools, disturbance of egg masses by humans, pets, and livestock are problems for the Spotted Salamander. This is a long-lived amphibian producing relatively few eggs and it may not breed every year.

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Climate Change
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Impacts of Roads or Trails

**Description of habitat problem(s):** The Four-toed Salamander has specialized breeding requirements that make it vulnerable to habitat disturbance. Any habitat conversion, alteration, or fragmentation that disrupts species’ ability to move between breeding and terrestrial sites, changes water/soil chemistry, temperature, pool hydroperiod, humidity, etc, may have negative effects. Road mortality can negatively impact migrating adults and dispersing juveniles, especially when located between terrestrial and breeding habitats. Climate change that affects hydroperiod and/or water temperature of breeding pools could have significant impacts on productivity.

**Non-Habitat Problems:**

- Genetics
- Pollution
Common Name: **Four-toed Salamander**
Scientific Name: **Hemidactylium scutatum**
Species Group: **Herp**

**Trampling or Direct Impacts**

*Description of non-habitat problem(s):* Loss of metapopulation structure leading to genetic isolation due to fragmentation of suitable habitats by roads or other non-permeable development is problematic. Widespread treatment of breeding pools to control West Nile Virus would likely have negative effects on many amphibians, including Four-toed Salamanders.

Common Name: Common Mudpuppy
Scientific Name: Necturus maculosus
Species Group: Herp

Conservation Assessment:

- Final Assessment: High Priority
- Global Rank: G5
- State Rank: S2
- Global Trend: G5
- State Trend: S2
- Extirpated in VT? No
- Regionally Rare? Yes

Assessment Narrative:

The Mudpuppy is native to Lake Champlain and the Burlington area is the source of the type specimen from the late 1700s. The Connecticut River population may be from an introduced source. Widespread lampricide applications in many Lake Champlain tributaries is a risk to Mudpuppies and losses have been documented, but not consistently. Surveying for Mudpuppies has proven to be difficult and our understanding of abundance, and even distribution, remains uncertain. A recommendation to list this species as threatened was not accepted by the Agency of Natural Resources.

This species appears to be restricted to the shoals and shallows of Lake Champlain and the lower reaches of tributaries to the lake. There is also a Connecticut River population that may not be native. Lampricide treatments in Lake Champlain (NY and VT) have killed wild mudpuppies. Specimens in some cage studies during treatments have survived and we do not fully understand why the effects have been so different between treatments. The USFWS has attempted to survey for Mudpuppies in and near Lake Champlain with little success.

Distribution:

Natural History Elements:
- Home Range: <1 ha
- Migrant? No
- Within watershed: Yes
- Within biophysical region: No
- Within VT: No
- Within Region: No
- Within US: No
- Outside US: No

Distribution Summary:

Primarily Lake Champlain and lower reaches of tributaries and Connecticut River. One record from Missisquoi River tributary well above falls line in Town of Fairfield.

Known Watersheds:
- CT-Ashuelot River
- CT-Bellows Falls Dam to Vernon Dam
- CT-White River to Bellows Falls
- Lake Champlain Direct

Possible Watersheds:
- CT-Johns River to Waits River
- CT-Waits River to White River
- Upper Connecticut
Necturus maculosus
Common Name: Common Mudpuppy
Scientific Name: Necturus maculosus
Species Group: Herp

Missisquoi River
Winooski River

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

The mudpuppy inhabits the bottoms of lakes and rivers up to 30 m deep. It avoids swiftly moving water and seems to be somewhat sedentary moving up to 252 m in its aquatic environment. There is some evidence of short distance seasonal migrations from shallows to pools or river channels.

**General Habitat Preferences:**

- Minimum Elevation (m): 25
- Maximum Elevation (m): 60
- Patch Size Requirements: Unknown
- Prefers large wetland complexes: ☐
- Prefers large expanses of grassland habitat: ☐
- Prefers habitat mosaics: ☐
- Prefers developed landscapes: ☐
- Prefers actively managed woodland: ☐
- Requires movement corridors: ☐
- Prefers large expanses of forest habitat: ☐

**Vegetation Categories Used:**

(see Appendix B for habitat, community & landscape organization and conservation summaries)

- Aquatic: Fluvial
- Aquatic: Lacustrine
- Aquatic: Large Lake Champlain Tribs Below Falls
- Aquatic: Lower CT River
- Aquatic: Man-Made Water Bodies

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Inadequate Disturbance Regime
- Sedimentation

**Description of habitat problem(s):** The mudpuppy's aquatic habitat can be fragmented by dam barriers and this habitat can be degraded by loss of cover and sedimentation.

**Non-Habitat Problems:**

- Disease
- Pollution
- Reproductive Traits
- Trampling or Direct Impacts

**Description of non-habitat problem(s):** Direct mortality has been documented due to some TFM lampricide applications in NY and VT. The Mudpuppy produces <200 eggs, which are deposited.
underwater to the underside of a rock or log. It does not reach reproductive maturity until about six years old. This is a long-lived species and survival of breeding adults is very important to the maintenance of populations. Some individuals are caught on hooks. A large botulism was reported in the Great Lakes in 2003.

### Research and Monitoring Needs

</tr>
<tr>
<td>Exirpated in VT?</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>Regionally Rare?</td>
<td>Unknown</td>
<td></td>
</tr>
</tbody>
</table>

**Assessment Narrative:**

The Fowler’s Toad is rare in Vermont (S1, SC). The Fowler's Toad has specialized habitat requirements and depends on habitat mosaics consisting of sandy shorelines and uplands adjacent to shallow breeding sites. Habitat loss due to succession is also a problem for this species.

### Distribution:

#### Known Watersheds
- CT-Ashuelot River
- CT-White River to Bellows Falls

#### Possible Watersheds
- CT-Bellows Falls Dam to Vernon Dam
- Deerfield, MA-VT
- Hudson-Hoosic Rivers

### Natural History Elements:

- **Home Range:** <1 ha
- **Migrant?** No
- **Within watershed:** Yes
- **Within biophysical region:** No
- **Within VT:** No
- **Within Region:** No
- **Within US:** No
- **Outside US:** No

### Distribution Summary:

The Fowler's Toad is primarily a species of the Atlantic Coastal Plain, its distribution in Vermont is limited to the lower Connecticut River valley, with populations documented at one site each in Vernon and White River Junction (Andrews 2001, Barker and Caduto 1984).

### Habitat Description:

Habitat Information is based on the following:

- **Limited Local Knowledge**
- **Extensive Local Knowledge**
- **Regional Literature**
- **General Literature**

Fowler’s Toad primarily inhabits well-drained sites, particularly floodplain forests and sandy deciduous woodlands along shorelines and river valleys, but may also occupy also gardens, lawns, and fields.
Common Name: Fowler's Toad  
Scientific Name: Bufo fowleri  
Species Group: Herp

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Climate Change
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Impacts of Roads or Trails

Description of habitat problem(s): The Fowler’s Toad has specialized habitat requirements that make it vulnerable to disturbance. Any habitat conversion, alteration, or fragmentation that disrupts species’ ability to move between breeding and terrestrial sites may have negative effects. Road mortality can negatively impact migrating adults and dispersing juveniles, especially when located between terrestrial and breeding habitats. Climate change that affects hydroperiod and/or water temperature of breeding pools could have significant impacts on productivity.

Non-Habitat Problems:
- Genetics
- Pollution
- Trampling or Direct Impacts
Vermont Department of Fish and Wildlife
Comprehensive Wildlife Conservation Strategy
Species Assessment Report

Common Name: Fowler's Toad
Scientific Name: Bufo fowleri
Species Group: Herp

Description of non-habitat problem(s): Known populations of this species occur in close proximity to humans, and in a region of the state that continues to see significant development pressure. Fragmentation of suitable habitats by roads or other non-permeable development may result in loss of metapopulation structure and leading to genetic isolation, especially considering the limited and localized populations of this species. Widespread treatment of breeding pools to control West Nile Virus would likely have negative effects on many amphibians, including Fowler’s Toad.

Final Assessment: High Priority  
Global Rank: G5  
Global Trend: Declining  
State Rank: S1  
State Trend: Declining  
Exirpated in VT? No  
Regionally Rare? Yes

**Assessment Narrative:**

This species was located in townships along northern Lake Champlain from Swanton/Alburg to Georgia in the 1970s. Today we struggle to find even a few individuals at a single location in Alburg. It is state-listed as endangered. We do not know where adults over winter and stay following the breeding season.

Habitat loss due to succession is also a problem for this species. Habitat loss from drainage of pools in agricultural fields. This species may be vulnerable to taking but isn't targeted directly by collectors. Species may also vulnerable to taking by mowing of agricultural fields. Habitat in Vermont seems to be flooded or ponded pasture with shrubs...not out in open with spring peepers. May be best to survey later in morning after peepers quiet down.

**Distribution:**

</tr>
</thead>
<tbody>
<tr>
<td>High Priority</td>
<td>G5</td>
<td>Declining</td>
<td>S1</td>
<td></td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Assessment Narrative:**

The state-endangered Spotted Turtle has only a single known location in Vermont and is a species of regional conservation concern, therefore this species is a SGCN.

The single know Spotted Turtle site in Vermont is compromised by surrounding landuse and a RR that bisects the wetland limits safe passage of the turtles. We are currently monitoring limiting factors at this site, which is believed to have a very small population.

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Climate Change
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Impacts of Roads or Trails

*Description of habitat problem(s):* Habitat problems of the Spotted Turtle include loss of wetland overwintering and foraging habitat, loss of nesting areas, fragmentation isolating populations and separating needed seasonal habitats, as well as road mortality. Climate change could affect the Spotted Turtle if a change in water regime results.

**Non-Habitat Problems:**
- Genetics
- Harvest or Collection
- Predation or Herbivory
- Reproductive Traits
- Trampling or Direct Impacts

*Description of non-habitat problem(s):* The Spotted Turtles is vulnerable to collection, nest predation, road mortality, and population rescue is unlikely. If close to humans, risks increase.
## Research and Monitoring Needs

Common Name: Wood Turtle  
Scientific Name: Clemmys insculpta  
Species Group: Herp  

Conservation Assessment:  
Final Assessment: High Priority  
Global Rank: G4  
Global Trend: Declining  
State Rank: S3  
State Trend: Declining  
Extirpated in VT? No  
Regionally Rare? No  

Assessment Narrative:  
The Wood Turtle is a species of regional conservation concern and possibly worthy of consideration as a federally listed species (NE Endangered Species and Wildlife Diversity Committee) and a species of special concern in Vermont. It is believed to still be widely distributed, but potentially declining throughout its range due to its long age to maturity and increasing loses of long-lived adults. It is still encountered over a wide region, which may be masking the conservation peril this species faces.  
The Wood Turtle is found in upland habitat adjacent to streams, providing it is not heavily developed or intensively used for agriculture. It is vulnerable to mowing of agricultural fields and to road mortality. Habitat loss due to succession is also a challenge for this species, but it seeks out and uses even small suitable patches withing woodlands. It is also at risk to collection.  

Distribution:

Lamoille River  
Mississquoi River  
Otter Creek  
White River  
Winooski River

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge☐
- Regional Literature☐
- General Literature ☐

The Wood Turtle is found in a landscape of rolling hills. Upland habitat adjacent to streams needs to be permeable to Wood Turtle terrestrial wanderings. It uses shrub swamps, alder swamps, and can use human-altered landscapes if not too severe, but it must have a suitable home stream. Home range can be calculated as less than a hectare if long-distance movements for females to nest or for males to patrol a river or stream to breed females (1.5 km) is not included.

moderate gradient streams w/ refuge sites, sand gravel & rock streambeds. Areas for egg laying

**General Habitat Preferences:**

- Open Peatlands
- Seeps and Pools
- Shrub Swamps
- Softwood Swamps
- Spruce Fir Northern Hardwood
Current Problems:  (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Habitat Succession

**Description of habitat problem(s):** Loss of upland habitat adjacent to Wood Turtle home stream is a real problem. It can tolerate a fair amount of succession providing some suitable patches remain. Although the Wood Turtle can use an agricultural landscape, too intensive a use such as row crops, is unsuitable. Habitat is being broken up by development and roads. Trails can bring more people into contact with Wood Turtles.

**Non-Habitat Problems:**
- Harvest or Collection
- Predation or Herbivory
- Trampling or Direct Impacts

**Description of non-habitat problem(s):** Wood turtles are susceptible to collection, egg predation, and road mortality, hence proximity to human habitation is a risk.

<td>Regionally Rare? No</td>
</tr>
</tbody>
</table>

**Assessment Narrative:**

The musk turtle is only recorded from the Champlain Valley of Vermont in about ten townships. It is small with limited dispersal capabilities. Water chestnut control harvesting is a potential limiting factor to this species. This species might be impacted by shoreline development that leads to loss of aquatic vegetation and suitable nesting sites (Harding 1997). In Vermont, ANR staff involved in water chestnut harvesting are aware of the potential to impact musk turtles that might be collected with the vegetation, and operate the harvester slowly and are on the lookout for turtles.

Common Name: Spiny Softshell (Turtle)
Scientific Name: Apalone spinifera
Species Group: Herp

Conservation Assessment:

Final Assessment: High Priority
Global Rank: G5
State Rank: S1
Global Trend: Declining
State Trend: Declining
Extirpated in VT? No
Regionally Rare? Yes

Assessment Narrative:

The Spiny Softshell Turtle is restricted to Lake Champlain in VT and PQ, and is not found elsewhere in New England. It is not known from the NY side of Lake Champlain. All other historical locations in Quebec have been lost and the Winooski River population in Vermont has been lost. Shoreline development has limited nesting and basking areas for this species.

The Softshell is a very strong swimmer, but it is restricted to habitats in or near Lake Champlain and is unlikely to gain immigrants from outside Lake Champlain. Habitat loss due to succession is also a problem for this species, but can be corrected with vegetative management and natural processes such as ice scour of nesting beaches. Increasing lake use is limiting this species directly by boat strikes and limiting habitat through lakeshore development, especially sea walls and riprap. Human disturbances limit basking and can chase nesting females away from nesting beaches. Egg predator populations are abnormally high due to lack of larger predators and trapping pressure, and are subsidized by humans in the form of increased food supplies (garbage, pet food, corn).

Distribution Summary:

The Softshell is currently restricted to Missisquoi Bay and surrounding areas of shore and lower reaches of rivers and creeks from Pike River to St. Alban's Bay and a smaller subpopulation is associated with the lower Lamoille River and surrounding lake.

Known Watersheds

Lake Champlain Direct
Common Name: **Spiny Softshell (Turtle)**  
Scientific Name: **Apalone spinifera**  
Species Group: **Herp**

**Habitat Description:**

Habitat Information is based on the following:  
- Limited Local Knowledge  
- Extensive Local Knowledge  
- Regional Literature  
- General Literature

The Spiny Softshell Turtle is a highly aquatic species inhabiting lakes, larger rivers, and associated wetlands. It utilizes logs, shorelines, and even artificial structures for basking as long as they receive sufficient solar radiation and are relatively free of disturbance. Wetlands are used in the spring for foraging. Softshells bask aerially and in shallow water.

**General Habitat Preferences:**

- Minimum Elevation (m): **28**  
- Maximum Elevation (m): **32**

**Vegetation Categories Used:**

(see Appendix B for habitat, community & landscape organization and conservation summaries)

- Aquatic: Lacustrine
- Aquatic: Lake Champlain
- Aquatic: Large Lake Champlain Tribs Below Falls
- Marshes and Sedge Meadows
- Shrub Swamps
- Upland Shores
- Wet Shores

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Habitat Succession
- Inadequate Disturbance Regime

**Description of habitat problem(s):** Shoreline development is the biggest habitat problem. Both nesting and basking substrate is lost. Natural processes that create and clear nesting areas along shoreline are now impaired. Dams can cut off upstream populations or even divide populations. Marinas or other deep water development can impact hibernacula.

**Non-Habitat Problems:**

- Pollution
- Predation or Herbivory
- Trampling or Direct Impacts

**Description of non-habitat problem(s):** Softshell Turtles are subject to intense nest predation due to high levels of nest predators and concentrated nesting in a few locations. The nesting sites are impacted by human disturbance during nesting by shoreline and water recreation and nearby camps. Activity on nesting beaches can directly impact eggs and we have documented one case of equipment being driven over nests.
and causing damage. Human disturbance limits basking opportunities and duration. Pollution may have played a role in the decline of the Winooski River population and there remains concern about contaminants in Lake Champlain and possible impacts from toxic blue-green algal booms.

Assessment Narrative:

The Five-lined Skink is an S1, state-endangered species, that is known from only three locations in West Haven, VT.

All Five-lined Skink sites in Vermont feature talus and exposed rock within a mile of Lake Champlain. Total records of individual sightings are fewer than 40. We have almost no data on their abundance and natural history in VT. We would benefit from data on distribution, behavior, seasonal movements, egg-laying sites, predators, food, population size, and microhabitat requirements.

**Distribution Summary:**

The Five-lined Skink is known from three locations in West Haven, VT.

**Known Watersheds**

- Lake Champlain Canal
- Lake Champlain Direct

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge ✓  
- Extensive Local Knowledge □  
- Regional Literature ✓  
- General Literature ✓

The Five-lined Skink is known currently only on talus slopes and nearby cliff faces, exposed rocky ridges, and rocky shorelines. The ridges are composed off a mixture of ledge, broken rock, and scattered juniper or hardwoods. All known sites have a south or southwestern exposure, low elevation, nearby water, and relatively warm climates for Vermont. Anecdotal historic reports mention the use of exposed faces of old buildings near...

**Vegetation Categories Used:**

(see Appendix B for habitat, community & landscape organization and conservation summaries)

Building or Structure
Cliffs and Talus
Oak-Pine Northern Hardwood
Other Cultural
Outcrops and Alpine

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

Habitat Alteration
Habitat Fragmentation
Habitat Succession
Impacts of Roads or Trails

**Description of habitat problem(s):** Five-lined Skinks need solar exposure, rock slides and fire may play a roll in keeping talus and ledges exposed. Development of lake-shore areas where the skink is found, removal of coarse woody debris, and introduction of cats could prove to eliminate local populations.

Skinks may move from denning sites on talus to feeding areas nearby. Short-distance seasonal movements seem likely. They do not seem to move across open field but rather short distances from talus to cliff, ridge, field edge, or lake-shore. Moderate traffic and wide roads could limit movements.

Future sources of coarse woody debris need to be maintained (old snags, large dead trees, etc.)

**Non-Habitat Problems:**

Genetics
Loss of Prey Base
Predation or Herbivory
Trampling or Direct Impacts

**Description of non-habitat problem(s):** Genetic isolation of populations could be a problem. Predation by cats or other introduced or subsidized predators could be a problem. Insecticide use could impact their prey base. When cold, lizards move slowly. Excessive trampling (intensive agricultural, residential, or recreational use could be a problem). Sites may have become isolated by large agricultural fields. Continuous sunny and rocky edge habitat seems to connect one large meta-population (Bald Mountain, Austin Hill, and adjacent rocky shorelines and talus slopes). The other known location (Dresden Narrows) may be isolated.
Common Name: **Five-lined Skink**  
Scientific Name: **Eumeces fasciatus**  
Species Group: **Herp**

Bibliography:

Klemens, M.K. 1993. Amphibians and reptiles of Connecticut and adjacent regions. State Geological and Natural History Survey of Connecticut, Bulletin No. 112 318 pp. (Unfortunately this is currently out of print.)

Mitchell, J.C. 1994. The reptiles of Virginia. Smithsonian Institution Press, Washington 352 pp. (This book provides excellent information on the species of reptile that we share with Virginia; most of our species are found in this book.)

Anecdotal historic reports in the southern Connecticut River Valley and on nearby ridges repeatedly speak of an Eastern Racer that was commonly seen twenty-five or more years ago, but it has not been seen in recent years. Habitat loss due to succession is likely negatively affecting this species.

The Eastern Racer is currently known from only one site in Vermont. It had not been documented in Vermont since 1985 and had been feared extirpated until relocated in 2003. It is an S1 species proposed for state-threatened status.

Anecdotal historic reports in the southern Connecticut River Valley and on nearby ridges repeatedly speak of an Eastern Racer that was commonly seen twenty-five or more years ago, but it has not been seen in recent years. Habitat loss due to succession is likely negatively affecting this species.

The currently known distribution of the Eastern Racer is a small area of SE Vermont. Its distribution prior to 1985 was somewhat more widespread but still fairly localized in southern Vermont.

**Known Watersheds**
- CT-Ashuelot River
- Deerfield, MA-VT

**Possible Watersheds**
- CT-Bellows Falls Dam to Vernon Dam
- CT-White River to Bellows Falls
- Hudson-Hoosic Rivers
- Lake Champlain Canal
- Lake Champlain Direct
- Otter Creek
The only known population of the Eastern Racer in Vermont uses early successional open ledge, grass, fern, and other herbaceous cover exclusively during the summer. It does move through short (30m) sections of woodlands between patches. It may move larger distances through woodlands to denning sites. It is known to den along ledges with talus slopes and exposed rock in other northern locations. One denning site in Vermont has been located.

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

The only known population of the Eastern Racer in Vermont uses early successional open ledge, grass, fern, and other herbaceous cover exclusively during the summer. It does move through short (30m) sections of woodlands between patches. It may move larger distances through woodlands to denning sites. It is known to den along ledges with talus slopes and exposed rock in other northern locations. One denning site in Vermont has been located.

**General Habitat Preferences:**

- Minimum Elevation (m): 30
- Maximum Elevation (m): 400
- Patch Size Requirements: > 1000 ha
- Prefers large wetland complexes: ☑
- Prefers large expanses of grassland habitat: ☑
- Prefers habitat mosaics: ☑
- Prefers developed landscapes: ☑
- Prefers actively managed woodland: ☑
- Requires movement corridors: ☑
- Prefers large expanses of forest habitat: ☑

**Vegetation Categories Used:**

(see Appendix B for habitat, community & landscape organization and conservation summaries)

- Cliffs and Talus
- Early Succession Upland Oak
- Grasslands and Hedgerows
- Outcrops and Alpine

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**

- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Habitat Succession
- Impacts of Roads or Trails

*Description of habitat problem(s):* This species probably expanded in numbers as Vermont was cleared. Open pasture, fields mowed by hand or horse, or fields not mechanically baled probably provided expanded habitat. Loss of early successional habitat, increased row cropping, and increasing speed and mechanization of cutting and bailing are believed to have limited appropriate habitat.

**Non-Habitat Problems:**

- Genetics
- Reproductive Traits
- Trampling or Direct Impacts

*Description of non-habitat problem(s):* Isolation of appropriate habitat patches may have led to genetic isolation. Increasing mechanization and speed of mowing and bailing causes direct mortality. Increasing road-building and traffic flow cause mortality and isolate populations. A mowed lawn does not support prey.
Vermont Department of Fish and Wildlife  
Comprehensive Wildlife Conservation Strategy  
Species Assessment Report

**Common Name:** Eastern Racer  
**Scientific Name:** *Coluber constrictor*  
**Species Group:** Herp

Increasing ATV use in rural areas is a direct problem. Direct persecution from encounters with humans and possibly dogs needs to be addressed. This is a long-lived species. Survival of breeding adults is therefore very important to the maintenance of populations.

Species Assessment Report

Common Name: Eastern Racer
Scientific Name: Coluber constrictor
Species Group: Herp

Bibliography:

Klemens, M.K. 1993. Amphibians and reptiles of Connecticut and adjacent regions. State Geological and Natural History Survey of Connecticut, Bulletin No. 112 318 pp. (Unfortunately this is currently out of print.)

Mitchell, J.C. 1994. The reptiles of Virginia. Smithsonian Institution Press, Washington 352 pp. (This book provides excellent information on the species of reptile that we share with Virginia; most of our species are found in this book.)

Common Name: **Eastern Rat Snake**  
Scientific Name: **Elaphe obsoleta**  
Species Group: **Herp**

### Conservation Assessment:

**Final Assessment:** High Priority  
**Global Rank:** G5  
**State Rank:** S2  
**Global Trend:**  
**State Trend:**  
**Exirpated in VT?** No  
**Regionally Rare?** Yes

### Assessment Narrative:

The Eastern Ratsnake is a S2 species that has been proposed for the status of state-threatened. Development, habitat fragmentation, road mortality, and direct persecution limit both Ratsnake populations in Vermont. The northern population appears to be entirely isolated. Anecdotal reports strongly suggest that both populations are declining.

### Distribution:

#### Natural History Elements:

- **Home Range:** < 100 ha
- **Migrant?** No
  - **Within watershed**: ✔
  - **Within biophysical region**: 
  - **Within VT**: 
  - **Within Region**: 
  - **Within US**: 
  - **Outside US**: 

#### Distribution Summary:

The Eastern Ratsnake is known from only two regions of VT. One meta-population can be found in western Rutland County and extending into southwestern Addison County. The second population is very localized on the border of Monkton, Bristol, and New Haven.

#### Known Watersheds

- Lake Champlain Canal
- Lake Champlain Direct
- Otter Creek

- **Extensive Local Knowledge**: 
- **Regional Literature**: ✔
- **General Literature**: ✔

This species dens in rocky talus slopes and possibly in rocky woodlands and along ledges at low elevation (<400m) with a southern or southwestern exposure. From these dens individuals travel to summer foraging areas that may be interior woodlands, edges, or wetland margins. Abandoned and low use buildings may be used.
**General Habitat Preferences:**

- Minimum Elevation (m): 30
- Maximum Elevation (m): 400
- Patch Size Requirements: > 1000 ha
- Prefers large wetland complexes: ☐
- Prefers large expanses of grassland habitat: ☐
- Prefers habitat mosaics: ☑
- Prefers developed landscapes: ☐
- Prefers actively managed woodland: ☐
- Requires movement corridors: ☑
- Prefers large expanses of forest habitat: ☑

**Vegetation Categories Used:**

- Building or Structure
- Cliffs and Talus
- Early Succession Upland Oak
- Grasslands and Hedgerows
- Hardwood Swamps
- Oak-Pine Northern Hardwood
- Other Cultural
- Outcrops and Alpine

**Current Problems:** (see Appendix C for definitions of problem categories)

**Habitat Problems:**
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Impacts of Roads or Trails

**Description of habitat problem(s):** Fragmentation of habitat by roads and ATV trails, development of low-elevation woodland fragments, and barriers to safe movement between denning and foraging areas all are problems.

**Non-Habitat Problems:**

- Genetics
- Reproductive Traits
- Trampling or Direct Impacts

**Description of non-habitat problem(s):** Some populations appear to be completely isolated, others may become so. This is a long-lived species, consequently direct persecution from humans and increased road mortality of adult breeders can outpace production. Roads attract and hold cold snakes as basking areas. Increasing road density and traffic are a problems. Increased ATV use in and near woodland fragments is known to cause mortality to snakes basking in trails. This species appears to travel up to a couple miles from denning areas, consequently it requires large habitat mosaics that are easily fragmented.

**Common Name:** Eastern Rat Snake  
**Scientific Name:** Elaphe obsoleta  
**Species Group:** Herp

---

**Bibliography:**

  (An excellent source for detailed information.)
  (The latest and most complete source for snakes.)
  (All our species are included.)
  (Most of our species are included.)
  (Visit the PARC website for more information: [www.parcplace.org](http://www.parcplace.org).)
  (Unfortunately this is currently out of print.)
  (This book provides excellent information on the species of reptile that we share with Virginia; most of our species are found in this book.)
  (One of a two excellent new snake resources.)
  (A reprint of an old classic.)
  (A standard text.)
Common Name: Northern Water Snake  
Scientific Name: Nerodia sipedon  
Species Group: Herp

**Conservation Assessment:**  
**Final Assessment:** Medium Priority  
Global Rank: G5  
State Rank: S3  
Extirpated in VT? No  
Regionally Rare? No

**Assessment Narrative:**

The Northern Water Snake is mainly a Champlain Valley species in Vermont, but also found in SE Vermont. This species is relatively large and aggressive, so is sometimes killed by humans.

This species does suffer some road mortality and is purposefully killed by some. It is usually associated with large wetlands of the Champlain Valley. Shoreline development may increase negative impacts from humans. Literature suggests pollution may be a problem (Harding 1997; Hunter, Calhoun, McCollough 1999). In some locations, the Northern Water Snake can be found in large numbers (e.g., Bristol Pond).

**Distribution:**

**Known Watersheds**
- CT-Ashuelot River
- Hudson-Hoosic Rivers
- Lake Champlain Canal
- Lake Champlain Direct
- Mississquoi River
- Otter Creek

**Possible Watersheds**
- CT-Bellows Falls Dam to Vernon Dam
- Lamoille River

**Natural History Elements:**
- Home Range: < 10 ha
- Migrant? No
- Within watershed □
- Within biophysical region □
- Within VT □
- Within Region □
- Within US □
- Outside US □

**Distribution Summary:**
Watersnake is known from the Champlain Valley, Shaftsbury, and Vernon.
Northern Water Snake

Scientific Name: *Nerodia sipedon*

Species Group: Herp

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Wetlands associated with permanent water bodies. Also used flooded meadows. Avoids deeply shaded areas (Hunter et al. 1999)

**General Habitat Preferences:**

<table>
<thead>
<tr>
<th>Preference</th>
<th>Value</th>
</tr>

Common Name: Northern Water Snake  
Scientific Name: *Nerodia sipedon*  
Species Group: Herp

**Bibliography:**

Klemens, M.K. 1993. *Amphibians and reptiles of Connecticut and adjacent regions.* State Geological and Natural History Survey of Connecticut, Bulletin No. 112 318 pp. (Unfortunately this is currently out of print.)

Mitchell, J.C. 1994. *The reptiles of Virginia.* Smithsonian Institution Press, Washington 352 pp. (This book provides excellent information on the species of reptile that we share with Virginia; most of our species are found in this book.)

Common Name: Brown Snake  
Scientific Name: Storeria dekayi  
Species Group: Herp

**Conservation Assessment:**

- **Final Assessment:** Medium Priority
- **Global Rank:** G5
- **State Rank:** S4
- **Global Trend:** Unknown
- **State Trend:** Unknown
- **Exirpated in VT?** No
- **Regionally Rare?** No

**Assessment Narrative:**

The Dekay’s Brownsnake is an S4 species in Vermont, but populations are small and highly localized.

The Brown Snake reaches its ecological limit across northern New England (Hunter et al. 1999), where it is less tolerant of disturbed sites and dependent upon habitat mosaics consisting of wetlands or riparian margins adjacent to upland forest overwintering sites.

**Distribution:**

**Natural History Elements:**

- **Home Range:** < 10 ha  
- **Migrant?** No  
- **Within watershed:** Yes  
- **Within biophysical region:** No  
- **Within VT:** No  
- **Within Region:** No  
- **Within US:** No  
- **Outside US:** No

**Distribution Summary:**

The Brown Snake is primarily found in the Champlain Valley, Taconics, and a few scattered records from the southern CT River Valley. It is widespread and more common in southern New England (Klemens 1993).

**Known Watersheds**

- CT-Ashuelot River  
- CT-Bellows Falls Dam to Vernon Dam  
- CT-Waits River to White River  
- CT-White River to Bellows Falls  
- Deerfield, MA-VT  
- Lake Champlain Direct  
- Lamoille River  
- Otter Creek  
- Winooski River

**Possible Watersheds**

- Hudson-Hoosic Rivers  
- Missisquoi River
Vermont's CWCS 9/7/2005 Appendix A5: Reptile & Amphibian SGCN

Common Name: Brown Snake
Scientific Name: Storeria dekayi
Species Group: Herp

Habitat Description:

Habitat Information is based on the following:

- Limited Local Knowledge
- Extensive Local Knowledge
- Regional Literature
- General Literature

Dekay’s Brown Snake primarily occupies wet woods and fields, sedge meadows, seeps, and wetland or stream margins adjacent to upland forest. They are typically found under a variety of cover objects, including logs, stones, brush piles, leaf litter, etc.

General Habitat Preferences:

<table>

Floodplain Forests
Grasslands and Hedgerows
Hardwood Swamps
Lawn, Gardens, and Row Crops
Marshes and Sedge Meadows
Northern Hardwood
Oak-Pine Northern Hardwood
Open Peatlands
Seeps and Pools
Shrub Swamps

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:

- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Impacts of Roads or Trails

**Description of habitat problem(s):** Any habitat conversion, alteration, or fragmentation that disrupts species’ ability to move between foraging and overwintering sites may have negative effects. Road mortality can negatively impact migrating adults and dispersing juveniles, especially when located between hibernaculum and foraging habitats. In Vermont this species appears less tolerant of disturbed habitats than in southern New England near the core of its range.

Non-Habitat Problems:

- Trampling or Direct Impacts

**Description of non-habitat problem(s):** This species often occurs in close proximity to humans, and its distribution is primarily in a region of the state that continues to see significant development pressure.
Common Name: **Brown Snake**
Scientific Name: **Storeria dekayi**
Species Group: **Herp**

Fragmentation of suitable habitats by roads or other non-permeable development may result in loss of metapopulation structure leading to genetic isolation and prevention of recolonization, especially considering the limited and localized populations of this species.

Klemens, M.K. 1993. Amphibians and reptiles of Connecticut and adjacent regions. State Geological and Natural History Survey of Connecticut, Bulletin No. 112 318 pp. (Unfortunately this is currently out of print.)

Mitchell, J.C. 1994. The reptiles of Virginia. Smithsonian Institution Press, Washington 352 pp. (This book provides excellent information on the species of reptile that we share with Virginia; most of our species are found in this book.)

The Eastern Ribbon Snake is one of the rarest of snakes in Vermont based on the number of known current sites. It seems to depend on a combination of a relatively warm, undeveloped lowland site and wetlands. This species requires wetland edges with sunny exposed basking sites in warm, low-elevation, largely undeveloped areas. The presence of nearby rocky woodlands and talus seems to increase the chances of finding this species.

Eastern Ribbon Snake is an S2 species in Vermont and is considered a species of special concern in Vermont. The Eastern Ribbon Snake is one of the rarest of snakes in Vermont based on the number of known current sites. It seems to depend on a combination of a relatively warm, undeveloped lowland site and wetlands.

It is currently documented from only six locations in Vermont: five in western Rutland County and one along the southern Connecticut River valley. A handful of historic records and sightings come from further north in the Lake Champlain basin and the Connecticut River Valley.

Habitat Information is based on the following:

- **Limited Local Knowledge**
- Extensive Local Knowledge
- Regional Literature
- General Literature

This species requires wetland edges with sunny exposed basking sites in warm, low-elevation, largely undeveloped areas. The presence of nearby rocky woodlands and talus seems to increase the chances of finding this species.

Species Assessment Report

Common Name: Eastern Ribbon Snake
Scientific Name: Thamnophis sauritus
Species Group: Herp

General Habitat Preferences:
- Minimum Elevation (m): 30
- Maximum Elevation (m): 400
- Patch Size Requirements: > 100 ha
- Prefers large wetland complexes: ✓
- Prefers large expanses of grassland habitat: □
- Prefers habitat mosaics: ✓
- Prefers developed landscapes: □
- Prefers actively managed woodland: □
- Requires movement corridors: ✓
- Prefers large expanses of forest habitat: □

Vegetation Categories Used:
Aquatic: Man-Made Water Bodies
Cliffs and Talus
Grasslands and Hedgerows
Marshes and Sedge Meadows
Oak-Pine Northern Hardwood
Seeps and Pools
Shrub Swamps

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Habitat Alteration
- Habitat Fragmentation
- Impacts of Roads or Trails
  Description of habitat problem(s): Conversion or drainage of wetlands, shoreline development, and fragmentation due to road density could all be problems.

Non-Habitat Problems:
- Genetics
- Loss of Prey Base
- Trampling or Direct Impacts
  Description of non-habitat problem(s): Some populations may be genetically isolated and others are becoming more so as a result of development. This species may be dependent on local amphibian populations that are known to vary annually. ATV use, increased traffic, cutting and bailing, and lawn mowing could all increase mortality significantly. It has not been located in moderately or heavily developed areas.

Final Assessment: Medium Priority  
Global Rank: G5  
State Rank: S4  
Global Trend:  
State Trend:  
Exirpated in VT? No  
Regionally Rare? No  

Assessment Narrative:  
Few people encounter this species and it is thought to be found less frequently than in the past. Little is known about its distribution in Vermont. Conservation status is uncertain, but this species probably should be s3 and is being considered a medium priority species.  

Habitat loss due to development is also a problem for this species, especially in the lowlands. In past large beaver meadows may have been connected. Mechanization of agriculture, lawn mowing, and roads all are likely impacts. In the southern Great Lakes Basin it is reported to be decreasing due to intensive conversion of its habitat to agricultural uses and pesticides (Harding 1997. The Amphibians and Reptiles of the Great Lakes Region)

Common Name: **Timber Rattlesnake**  
Scientific Name: **Crotalus horridus**  
Species Group: **Herp**

**Conservation Assessment:**

<table>
<thead>
<tr>
<th>Final Assessment: High Priority</th>
<th>Global Rank: G4</th>
<th>Global Trend:</th>
</tr>
</thead>
<tbody>
<tr>
<td>State Rank: S1</td>
<td>State Trend:</td>
<td>Extirpated in VT? No</td>
</tr>
</tbody>
</table>

**Assessment Narrative:**

The Timber Rattlesnake is a state-endangered S1 species that was historically known from a much wider range in VT and the region.

It is currently documented from only two denning areas in Vermont. The species had a bounty on it until 1971. The bounty has been lifted but takings still occur. Its habit of denning communally at den sites which are now quite widely known make it unusually vulnerable to takings. This behavior also provides opportunities for geographically targeted protection. Since it is a venomous species, it is more widely feared and persecuted. As its name implies, it depends on warm low-elevation woodlands that are sparsely populated.

**Distribution:**

![Biophysical Regions in Vermont](image)

**Natural History Elements:**

- **Home Range:** <1000 ha
- **Migrant?** No
- **Within watershed** Yes
- **Within biophysical region** No
- **Within VT** No
- **Within Region** No
- **Within US** No
- **Outside US** No

**Distribution Summary:**

Extant populations of Timber Rattlesnake are restricted to areas near the southern portion of Lake Champlain in western Rutland County. Populations in other parts of the state have been lost.

**Known Watersheds**

Lake Champlain Canal  
Lake Champlain Direct

**Habitat Description:**

Habitat Information is based on the following:

- Limited Local Knowledge  
- Extensive Local Knowledge
- Regional Literature
- General Literature

The Timber Rattlesnake is currently documented only from western Rutland County. In this region it dens on south or southwest facing talus slopes which are near rocky ridges with exposed ledge and large undeveloped or sparsely developed areas of oak-hickory woods.

- Mine
- Oak-Pine Northern Hardwood
- Outcrops and Alpine
- Subterranean

(see Appendix B for habitat, community & landscape organization and conservation summaries)

Current Problems: (see Appendix C for definitions of problem categories)

Habitat Problems:
- Conversion of Habitat
- Habitat Alteration
- Habitat Fragmentation
- Impacts of Roads or Trails

Description of habitat problem(s): The Timber Rattlesnake uses large contiguous woodland areas adjacent to their dens. Heavy agricultural or residential use, or conversion to open land are all problems. All remaining areas are adjacent to large sparsely-roaded woodlands. Heavy ATV use, increased traffic, or increased road-density are all problems. Lowland wooded patches are popular building sites and are becoming increasingly fragmented.

Non-Habitat Problems:
- Genetics
- Harvest or Collection
- Reproductive Traits
- Trampling or Direct Impacts

Description of non-habitat problem(s): One of the two known Timber Rattlesnake populations may be isolated from genetic exchange. Although venomous, this species is still illegally collected for various purposes and snakes that have been killed are regularly reported. Known traditional den sites and predictable patterns of behavior make the species very vulnerable to collection and persecution. Birthing sites also appear to be limited and traditional. This is a long-lived species that does not reproduce every year. Consequently, loss of breeding adults is more of a problem to the sustainability of the species. Heavy ATV use, increased traffic, and heavy recreational use along ridges during key time-periods is also a problem. Since this species is venomous, it is often feared and killed when found near residences.

Appendix A6
Plant Species of Greatest Conservation Need
Vermont's Plant Species of Greatest Conservation Need

Plant Species of Greatest Conservation Need: 577 of approximately 2,000 vascular and non-vascular species.

Vermont's plant SGCN list includes all species ranked S1 (critically imperiled) and S2 (imperiled) and a very few others that warrant concern. Those SGCN also on the New England Plant Conservation Program list of regionally rare plants will be ranked High Priority. All others were ranked medium priority. Plants are not eligible for State Wildlife Grant funds. We expect that community and landscape level conservation will provide secondary benefits including addressing the needs of many plant Species of Greatest Conservation Need.

Vermont’s list of Species of Greatest Conservation Need (SGCN) comprises 144 vertebrate species (including chestnut sided-warbler, lake sturgeon, and spotted salamanders) as well as 192 invertebrate species (including tawny emperor butterflies, cobblestone tiger beetles, and giant floater mussels). Developing individual conservation plans for each SGCN would have been exhausting and impractical. Moreover, attempts to implement the more than 300 plans would be impossible due to insufficient resources and the high overall cost, resulting from the inefficiency of implementing many uncoordinated plans (not to mention problems reminiscent of the Keystone Cops stemming from the hundreds of biologists in the field bumping into each other).

Fortunately an easier, cheaper, and more efficient approach to addressing the needs of our Species of Greatest Conservation Need exists. That method consists of designing and implementing conservation efforts at multiple scales. For example, wildlife managers have been creating edge habitat for decades (Smith 1980) where, for example, an early successional stage of forest borders later successional forest. They do this because research shows that this improves conditions for deer, rabbit, turkey, ruffed grouse and several other species. In this example management actions were targeted at the habitat level.

Similarly, research in the 1960’s and 1970’s indicated that pesticides such as DDT so weakened the eggs of loon, osprey, peregrine falcons and many other birds of prey that eggs were collapsing under the weight of expectant parents. Not only did this add to nationwide population crashes, it also impeded restoration efforts because the pesticides remained in the birds for years. Action taken at the state and federal level—the regulation of pesticides—eventually helped these species and loon, osprey, peregrine falcon were finally removed from the Vermont’s endangered species list in April of 2005.

Following this approach, we began at the species level by assessing SGCN individually. Then SGCN were organized by taxonomic group and by habitat usage with habitats grouped by vegetation type. This resulted in conservation strategies at five levels (table 4-1). Some species will always require specific conservation attention, such as those that are very rare, those that are declining across their range, those that aggregate for breeding, and those that require large home ranges. Their needs are addressed at the Species Level. Other species’ needs can be met by the long-term conservation of high quality habitats and communities used by these species (the Community Level). Still other species will require conservation at the scale of wildlife travel corridors and large forest blocks (the Landscape Level).

### Selection of Classification Systems

Though great strides have been made in developing vegetation classification systems that function at the site, landscape, region and national scales (Barnes 1979, Allen and Start 1982, Forman and Godron 1986, Cleland et. al 1997, Grossman et. al 1998) they are incomplete. In particular, no system satisfactorily integrates aquatic and terrestrial communities and cultural habitats\(^1\) used by wildlife. The efforts of every

---

\(^1\) Cultural habitats are communities and sites that are either created and/or maintained by human activities or are modified by human influence to such a degree that the physical condition is substantially different from what existed prior to human influence (adapted from Reschke 1990)
state, however, in development of their Action Plan greatly improve our prospects and plans are underway for coordination and information sharing once states' Action Plan reports are approved (IAFWA 2005).

In lieu of a unified habitat classification system, Vermont's Action Plan technical teams utilized the best features of five peer-reviewed vegetation classification systems that can be crosswalked with those used in other states to support broader scale conservation efforts—regionally, nationally, and internationally. Forest Cover Types (Eyre 1980) and U.S. Forest Service Forest Inventory & Analysis Types (USDA 2003) were used for early successional stage forests. Natural Communities (Thompson and Sorenson 2000) were the basis most terrestrial vegetation. "A Classification of the Aquatic Communities of Vermont" by Langdon et al. (1998) was adapted for aquatic community designations and cultural habitats1 were adapted from Reschke (1990). Landscape scale communities were adapted from Poiani et al. (2000).

One hundred 120 aquatic and natural community types, cultural habitats and land cover types, capturing most of the habitat required by SGCN were selected from the five systems (table 4-2). Each was assigned to one of 22 categories. Because Lake Champlain and the Connecticut River harbor most of the fish diversity in Vermont, these two waterbodies were broken out from the taxonomy to provide for a more targeted assessment. Technical teams then developed assessment summaries for each that includes descriptions and general locations; current conditions; desired conditions based on the needs of associated SGCN; priority problems; conservation strategies to address problems (along with the identification of potential conservation partners and funding sources); and a listing of relevant plans and planning processes pertinent to a habitat type. (Appendix B)

In addition, three landscapes were selected (forest, riparian, and fluvial/stream) to address connectivity needs of many SGCN as well as the needs of wide-ranging SGCN. Assessment summaries were also completed for each landscape (see this chapter).

Successional Stages, Species of Greatest Conservation Need and the Action Plan

Plant succession produces cumulative change in the types of plant species occupying a given area through time. It is complicated by factors such as disturbance (large and small), local conditions, seed banks and soil legacies (Oliver 1981). A highly simplified timeline begins when land is cleared. Pioneer species typically return first followed by other species generally better adapted to the new and changing conditions created by the previous suite of species. Given sufficient time and appropriate conditions the area moves roughly through early, middle, and late successional stages—often referred to as mature or old growth. A disturbance, if sufficiently large, can re-set the clock anytime and succession begins again. The best known examples are forest succession but it occurs in virtually all vegetated areas. For example, lichen communities on granite mountaintops experience successional changes (Wessels 2002).

Succession can significantly impact habitat for Species of Greatest Conservation Need and other wildlife as in the edge habitat example noted earlier. Generally as succession moves from early to late stages some wildlife will lose out (e.g., spruce grouse, woodcock, cottontail rabbit) and others will benefit (e.g., marten, northern goshawk). Others still prefer a mix of successional stages in appropriate configurations (e.g., black bear, lynx).

Over the past two centuries the mix of successional stages available to Vermont's wildlife has changed dramatically in both distribution and abundance. Though precise estimates (current and historic) are unavailable, prior to 1800 a significant percentage of Vermont's forests were in late-successional stages (>150-300 years and older). One-hundred years later early-successional stages (1-15 years) dominated the state and today mid-successional forests (60-100 years) are most abundant. Wildlife populations have responded in turn. Vermont's SGCN list contains relatively few species requiring mid-successional forests and more that thrive in early and late-successional representations.
Because the loss of late-successional forests in the eastern US occurred prior to the advent of modern wildlife biology and the current scarcity of later-successional stages (particularly northern hardwood forest types) our understanding how wildlife utilized these stages is not as advanced as our knowledge of wildlife in early successional stages. Historic records and research in late-successional areas elsewhere indicate that the distribution and abundance of some wildlife species was much greater when late-successional forests were in greater abundance—even if these species can survive without them. Given the lack of this condition on the landscape it is advisable to increase its availability to wildlife.

The habitat, community and landscape summaries that follow here and in Appendix B address habitat the needs of Species of Greatest Conservation Need that use that vegetation type in one or more successional stages. Conservation strategies address the particular successional stage needs well those species that prefer a mosaic of successional stages.

Floodplain Forest Summary

Characteristics and Location
Floodplain forests are usually dominated by silver maple or occasionally sugar maple, with abundant ostrich fern or sensitive fern. They are closely associated with river and lake floodplains and have exposed mineral soils of alluvial origin.

Natural communities of the Floodplain Forest include: Silver Maple-Ostrich Fern Riverine Floodplain Forest, Silver Maple-Sensitive Fern Riverine Floodplain Forest, Sugar Maple-Ostrich Fern Riverine Floodplain Forest and Lakeside Floodplain Forest.

Natural Communities of the Floodplain Forest:

Silver Maple-Ostrich Fern Riverine Floodplain Forest: This forest is found in the floodplains of moderate-gradient rivers. Silver maple and ostrich ferns are the dominant species and the soils are typically well drained sandy alluvium. Boxelder may be abundant in young forests.

Silver Maple-Sensitive Fern Riverine Floodplain Forest: These forests occur in the floodplains of large, low-gradient rivers. Silver maple is the dominant tree, but green ash and swamp white oak may be present. Sensitive fern and false nettle are characteristic. Soils are moist, typically mottled, silty alluvium.

Sugar Maple-Ostrich Fern Riverine Floodplain Forest: This uncommon floodplain forest type occurs along small to moderate sized high gradient rivers in areas of calcium-rich bedrock. Sugar maple, white ash, basswood, boxelder, and ostrich fern are common. There can be a diverse herbaceous layer. Soils are well drained sandy alluvium. Many examples of this community are uplands.

Lakeside Floodplain Forest: These forests occur primarily within the flooding zone of Lake Champlain. Silver maple and green ash are the dominant trees. Herbs include sensitive fern, false nettle, marsh fern, white grass, and Tuckerman's sedge. Surface organic layers are present in the moist silty soils and there are mottles near the surface.

Floodplain Forest Condition
Historical Perspective: Although there is little specific information on distribution and composition of floodplain forests prior to European settlement in the region (Siccama 1971), it is expected that they covered large areas and were likely continuous bands of forest extending unbroken for miles along all of our major rivers. Forests of towering silver maple and American elm likely covered many of the active floodplains, with more diverse forests of sugar maple, red oak, and other species on higher terraces of former floodplains. (Sorenson et al. 1998). Although their total numbers were relatively small, evidence suggests that the Abenaki people that lived in Vermont concentrated their villages and agriculture on and adjacent to the floodplains of the Connecticut River, other major rivers, and Lake Champlain (Klyza and Trombulak 1999).
**Current Condition:** High quality floodplain forests are now uncommon in Vermont because the vast majority of the floodplain forest in Vermont and the region has been converted to agricultural use. Floodplains have been prized as agricultural lands because of their high soil fertility associated with annual flooding and deposition and because of the absence of stones. As a result of their high value as agricultural lands, floodplain forests are now limited to fragments of their original size. The small percentage of riverine floodplains remaining in a forested condition is illustrated for Franklin County by a comparison made between the area of alluvial soils identified by the Natural Resources Conservation Service (USDA 1979) and the area of floodplain forests identified in a Vermont Fish and Wildlife Department floodplain forest inventory project (Sorenson et al. 1998). Although approximate, this comparison indicates that as little as 11% of the floodplains in Franklin County remain in a forested condition.

Significant changes to the flooding regimes of floodplain forests result from dam operation and the construction of roads, bridges, and culverts along rivers and in floodplains. Furthermore, the disturbed nature of many of the floodplain sites makes them vulnerable to invasive exotic plant species, such as goutweed (*Aegopodium podagraria*), garlic mustard (*Alliaria petiolata*), dame’s-rocket (*Hesperis matronalis*), honeysuckle (*Lonicera* spp.), and Japanese knotweed (*Polygonum cuspidatum*) (Sorenson et al. 1998).

** Desired Condition (SGCN Needs):** Floodplain forest is essential to those SGCN that require habitat mosaics of aquatic and riparian areas and upland forest. Several of the species associated with floodplain forests require a riparian mosaic that depends upon functioning floodplain wetlands (e.g., pied-billed grebe, *Odonata*, American black duck); many of which are most abundant in the floodplains of larger river systems. Other species such as the water shrew and spotted salamander use floodplain forest directly adjacent to the stream or river. Lastly, there are some species that require large (10-1000ha) contiguous blocks of forested habitat along stream and rivers—these range from the bald eagle to the mink to the wood turtle. In all, floodplain forest provides habitat for a total of 49 wildlife SGCN and 28 plant SGCN. Desired conditions include functional floodplain forests in healthy examples (mature, unfragmented) distributed across their range. High water quality is also an essential element of floodplain forest quality. Focus should be give to the largest examples.

Hardwood Swamp Summary

Characteristics and Location
Hardwood dominated swamps are the most common swamp type in the state. They are especially common in the warmer regions of the state on flatter topography and so reach their largest size and greatest abundance in the Champlain Valley and are least frequent in the Northeast Highlands. While two of the seven types are widely distributed, two others are restricted to a few biophysical regions, and the remaining three occur primarily in only a single biophysical region.

Hardwood swamps provide a number of functions, including flood storage, water quality protection, and fish, wildlife, and endangered species habitat. Because of their more open, deciduous canopy, hardwood swamps have more significant understory development than do softwood dominated swamps. This feature, along with their characteristic hummock and hollow topography, creates a landscape mosaic that provides an abundance of microhabitats.

The hardwood swamp formation includes the seven following natural community types:

**Red Maple-Black Ash Seepage Swamp**: This is the most common hardwood swamp type in the state. It occurs in all biophysical regions as either small or large patches. Although they occur in various settings, this natural community type is closely associated with groundwater seepage and does not typically experience surface flooding of long duration. While red maple is typically the dominant tree, black ash is very characteristic of this community. There are also other tree species present and well developed shrub and herbaceous layers.

**Red Maple-Sphagnum Acidic Basin Swamp**: This is another common swamp type that is widely distributed throughout the state. Typically it occurs in poorly drained basins with deep organic soils. Groundwater seepage is absent and the permanently saturated soils tend to be quite acidic. Since they occur in basins, most of these basin swamps are small and typically have no inlet or outlet streams. Red maple is the dominant tree, often with a co-dominance of yellow birch and various softwoods. The shrub layer is well developed, but the herb layer is less diverse, often with dominance by cinnamon fern. Moss cover typically approaches 100%.

**Red Maple-Northern White Cedar Swamp**: This uncommon community type exists as large patches mostly in the western part of the state. This community is limited to areas of calcareous bedrock and is often associated with floodplains, especially in the Champlain Valley. Although it can also occur in isolated basins, it can form huge wetland complexes where it is associated with larger rivers. Red maple, white cedar, and black ash typically dominate the canopy. Both the shrub and herbaceous layer tend to be sparse depending upon the degree of shading and the abundance of water-filled hollows.

**Calcareous Red Maple-Tamarack Swamp**: This is a rare community type that is restricted to areas of calcareous groundwater seepage. It is mostly restricted to the Vermont Valley with only a few examples in other biophysical regions. It typically occupies small isolated basins, but may also occur as part of a large wetland complex. Red maple and tamarack
dominate the canopy that can range from nearly closed to very open. In the latter situation, especially, a diversity of shrubs, herbaceous, and bryophyte species flourish.

**Red or Silver Maple-Green Ash Swamp:** This uncommon natural community type is largely restricted to the Champlain and Vermont Valleys. It occurs as large patches mostly associated with Lake Champlain. This swamp type typically undergoes extensive spring flooding that often results in saturated soils throughout the growing season. Although silver maple typically dominates, red maple and green ash may be very abundant. Both the shrub and herbaceous layer are well developed.

**Red Maple-Black Gum Swamp:** This rare community type occurs as small patches. It is mostly restricted to the southeastern part of the state with a few outliers in other regions. It occurs in small basins that are isolated from surface waters and that contain deep, saturated organic soils. Red maple and black gum co-dominate, but hemlock, yellow birch, and red spruce are also common.

**Red Maple-White Pine-Huckleberry Swamp:** This is a very rare natural community type that is restricted to the Champlain Valley. All known examples occur near the center of much larger wetland complexes. The canopy is dominated by red maple and white pine, but the most striking feature is the dense cover of huckleberry below. Typically, cinnamon fern dominates the herbaceous layer.

**Hardwood Swamps Condition**

**Current Condition:** Although still relatively common in the state, hardwood swamps were formerly even more abundant. The primary activities resulting in loss of hardwood swamps were commercial and residential road development and road construction. Presently, agricultural conversion results in the greatest loss of swamps. Although protected by the Vermont Wetland Rules, many smaller examples are not mapped and therefore not protected under the regulations. Since many of these swamp types are most abundant in the lower, warmer regions of the state, they are subject to hydrologic impairment and incremental loss along the edges as the area around them is developed.

The primary problems to SGCN include agricultural conversion, invasion by exotics, altered hydrology, development and unrestricted logging.

**Desired Condition:** Forested wetlands provide habitat for a number of SGCN in the state. Hardwood dominated examples are especially diverse since they tend to be at lower elevations and in warmer areas of the state than coniferous swamps. A total of 36 SGCN animals and 43 plant SGCN rely on one or more of these natural communities to provide habitat. Several of the species associated with hardwood swamps also require a habitat mosaic that depends on functioning swamps. Desired conditions include functional hardwood swamps in healthy examples (mature, unfragmented) across the distribution of their range. High water quality is also essential to habitat quality. Focus should be give to the largest examples.
### Species of Greatest Conservation Need in Hardwood Swamps

#### High Priority
- American Black Duck (Anas rubripes)
- Canada Warbler (Wilsonia canadensis)
- Fowler’s Toad (Bufo fowleri)
- Spotted Turtle (Clemmys guttata)
- Wood Turtle (Clemmys insculpta)
- Eastern Rat Snake (Elaphe obsoleta)
- Bog/fen/swamp/marshy pond Odonata group
- Eastern Pipistrelle (Pipistrellus subflavus)
- Pygmy Shrew (Sorex hoyi)

#### Medium Priority
- Blue-winged Teal (Anas discors)
- Great Blue Heron (Ardea herodias)
- Long-eared Owl (Asio otus)
- Red-shouldered Hawk (Buteo lineatus)
- Veery (Catharus fuscescens)
- Chimney Swift (Chaetura pelagica)
- Rusty Blackbird (Euphagus carolinus)
- Black-crowned Night-heron (Nycticorax nycticorax)
- Osprey (Pandion haliaetus)
- Pied-billed Grebe (Podilymbus podiceps)
- Blue-spotted Salamander (Ambystoma laterale)
- Spotted Salamander (Ambystoma maculatum)
- Four-toed Salamander (Hemidactylium scutatum)
- Brown Snake (Storeria dekayi)
- Cinereus or Masked Shrew (Sorex cinereus)
- Black Bear (Ursus americanus)

**SGCN Notes:** Plant SGCN not listed here 43. The SGCN invertebrate group listed here contains numerous species. For more information about a specific Species of Greatest Conservation Need see that species' assessment summary in Appendix A.

Softwood Swamps Summary

Characteristics and Location
Most softwood swamps in Vermont are situated at higher elevations in the cooler regions of the state. The one exception are hemlock swamps which behave more like hardwood swamps and are located in the lower, warmer portions of the state. Because of the dense shading in softwood swamps, the understory shrub and herbaceous layers are generally quite sparse. Conversely due to these same moist shady conditions, bryophyte cover tends to be quite abundant. All of the natural communities in this formation occur as small patches on the landscape with the exception of spruce-fir tamarack swamps which occur as large patch communities.

There are four types of natural community included within the softwood swamp group

Northern White Cedar Swamp: This is an uncommon natural community type that is associated with calcareous bedrock and groundwater seepage that makes the dissolved minerals available to the plants. Although it occurs in most of the state’s biophysical regions, this community is more abundant in the northern half of the state since white cedar declines to the south. In addition to white cedar, balsam fir may be abundant, but the dense shading results in a sparse shrub and herb layers. Only bryophytes attain abundance in these swamps.

Spruce-Fir-Tamarack Swamp: This uncommon natural community is totally absent from the warmer parts of the state. They typically occupy basins that are isolated from surface water movement and have deep organic soils. The canopy is dominated by red or black spruce, fir, and tamarack in varying abundance. Generally more tamarack is indicative of more mineral rich conditions while more black spruce is indicative of deeper peat and less enriched conditions. Despite the deep shade, a number of tall shrubs persist here, especially mountain holly and wild raisin. Herbs are sparse whereas bryophytes proliferate in the cool, moist conditions.

Black Spruce Swamp: As the peaty soils become deeper and increasingly acidic and saturated, black spruce begins to replace the less tolerant red spruce. This community is restricted to only the coldest locations where they occupy basins that have gradually accumulated peat over the millennia. Black spruce dominates the canopy which is generally rather low and sparse. These swamps have low shrub and herbaceous diversity due more to the cold, wet, acidic conditions than shading. In openings, low shrubs characteristic of bogs may be common, but bryophytes are ubiquitous throughout the community.

Hemlock Swamp: This uncommon swamp is absent from the Northeast Highland and Northern Piedmont biophysical Regions. They typically occupy basins that receive some mineral enrichment either through groundwater seepage or surface water. Generally the hemlock is associated with varying amounts of yellow birch, red maple and black ash. The dense canopy allows for few shrubs or herbs to survive; instead the ground is covered by ferns and bryophytes.

Softwood Swamps Conditions
Current Conditions: Softwoods swamps have been less impacted than either hardwood swamps or floodplain forest communities due to their location in the colder regions of the state.
and their generally saturated peat soils. As with the other two wetland types, softwood swamps also receive some protection from the Vermont Wetland Regulations. Nonetheless, they are still limited by habitat degradation and alteration, hydrologic impairment, and sedimentation from development on the fringes and in the watershed, road construction, and unrestricted logging. Exotic species, and herbivory, especially by moose, are also a concern. A potentially major problem for hemlock swamps is the presence in nearby Massachusetts of the hemlock wooly adelgid, an introduced insect that could devastate the Vermont's hemlocks.

**Desired Conditions:** The four natural communities in softwood swamp formation provide habitat for 26 SGCN animals. This includes a large number of birds, but also some turtles and salamanders. A total of 33 plant SGCN occur in softwood swamps; not surprisingly, the majority of which are bryophytes which thrive in the cool, moist, shady conditions. Only spruce-fir-tamarack swamps occur as large patches; however this community and northern white cedar swamps are often included within much larger wetland complexes. Three of the four community types exist as small patches, they are more easily protected; however protection would need to extend beyond the wetland boundary to include at least a portion of the watershed and should include connectivity to softwood swamps. In such situations protection would need to apply to the entire complex. Desired conditions include functional softwood swamps in healthy examples (mature, unfragmented) across the distribution of their range High water quality is also essential to habitat quality.

Vernal Pools & Seeps Summary

Vernal pools are small, open-water wetlands that are filled by rain and snowmelt in spring or fall and are typically dry during the summer months. Such a pool is usually contained within a small forested basin, has no permanent inlet or outlet, and does not support predaceous fish. Forested swamps may also contain vernal pools in small depressions. During particular wet growing seasons, temporary pools may persist without drying completely. Years of filling and drying result in a unique type of set of conditions that supports a variety of wildlife specialized to take advantage of these conditions. Vernal pools are often rich in unique insects, molluscs, and other invertebrates, as well as amphibians. When conditions are favorable, vernal pools are often used by mole salamanders and wood frogs for breeding.

Seeps occur on slopes or at the bases of slopes in upland forests. Groundwater discharge is evident at the seep margin. Scattered trees may be present but canopy closure is usually from the adjacent forest. Certain species are adapted to the living in these conditions, including some invertebrate and plant SGCN.

Vernal Pools & Seeps Condition

Current Condition: Vernal pools and the wildlife that that use them face many problems, including direct loss of pools, degradation of pool quality, and alteration of the surrounding upland habitat. Hikers, their pets, and recreational vehicles that enter vernal pool risk destroying amphibian eggs and larvae and invertebrate SGCN. In addition, recreational vehicles that enter vernal pools can destroy the soil structure that is so important to maintaining these pools and the species that depend on them. Alterations within the forested basin that surrounds a pool can have significant impacts on the pool's hydrology and its species. Reduction in the volume of water that fills the pool means that drying will occur sooner. Loss of the adjacent canopy trees increases the solar energy reaching the pool, causing water temperature to rise more rapidly and drying the pool earlier in the warm season than usual. Premature drying has a negative impact on the invertebrates and young amphibians that require a minimum length of time (up to 4 months or more) to complete critical life stages. Removal of too many mature trees and downed logs in the surrounding upland habitat can impair the forest floor used by pool-breeding salamanders and frogs. Ditches and vehicle runs in the surrounding forest often intercept spring migrating adults, luring them to lay eggs in spots that can dry well before the young can leave the water. Road construction or increased road traffic that bisects the upland amphibian habitat surrounding a vernal pool often results in the death of many of these animals as the make their annual migrations between the terrestrial and aquatic environments. The recent arrival, of and public fervor over, West Nile Virus may result in vernal pools being targeted for mosquito control. This may include biological controls, chemical pesticides, and possibly draining.

Seeps face problems similar to those of vernal pools. Activities that alter the hydrology of a seep to even a minor degree can eliminate the characteristics required by some wildlife species. The ecological significance of seeps (and vernal pools) is often not recognized during development planning, with the result being direct loss of these features.
Desired Condition (SGCN Needs): Functional vernal pools are those examples that are intact, well-buffered and interconnected to ensure productivity and movement of species associated with vernal pools. Spotted salamanders, blue-spotted salamanders, Jefferson salamanders, and wood frogs all use vernal pools for breeding. They spend almost their entire lives in the surrounding upland forests, moving up to 300 meters or more from the pool. The adults return for a brief period in the spring to leave their eggs. Water depth must be great enough to cover the egg masses (generally 30cm or more) and provide continuous aquatic habitat until the young leave the pool (3-4 months, depending on the species and location). The terrestrial adults and juveniles can be found under cover material (logs, rocks, stumps) and in animal burrows in moist forest soils that have adequate leaf litter. Spotted turtles are seasonal users, foraging in vernal pools in the early spring. They require large wetland complexes and move between wetlands through the warm season. There are several insects, snails, fingernail clams, fairy shrimp, and other invertebrates that use vernal pools for their entire life cycle. During the dry months, these animals or their eggs remain on or under the soil surface, awaiting the return of water to the pool depression. Many other SGCN use vernal pools seasonally but do not require them.

Seeps are home to a few specialized SGCN as well as many more common species. The gray petaltail is a rare dragonfly that lays its eggs in forested seeps, where the nymphs remain and feed until reaching adulthood. Eastern Jacob’s ladder is a threatened plant that is closely associated with seeps in Vermont.

Open Peatlands Summary

**Characteristics and location**

Open peatlands are wetlands that accumulate peat, a type of soil which consists of partially decomposed organic matter. These wetlands are permanently saturated with a stable water table at or near the soil surface, creating a nearly anaerobic soil environment. Seasonal flooding is generally lacking in these wetlands and mosses and liverworts are abundant. With the exceptions of Black Spruce Woodland Bogs and Pitch Pine Woodland Bogs, trees are generally absent or sparse due to the very low availability of dissolved oxygen and minerals in the soil. Bogs are a type of peatland with slightly raised surfaces that receive most of their water from precipitation, have acidic waters poor in minerals and nutrients, and are dominated by sphagnum mosses, heath shrubs, and in some areas black spruce. Fens, on the other hand, have slightly acidic to slightly basic mineral-rich waters from groundwater discharge and seepage, may be flat or gently sloping, and are dominated by sedges, grasses, and non-sphagnum mosses. Water in fens generally has higher oxygen concentrations than in bogs resulting in greater peat decomposition. There is a continuum, however, in the variations between bogs and fens.

Seven different natural community types are included in this group, all of which are considered rare:

**Dwarf Shrub Bog**: These are open, acid wetlands with few trees and are dominated by heath shrubs and sphagnum moss. Size ranges from one to 600 acres in isolated kettlehole basins and as inclusions in larger wetland complexes. They occur throughout Vermont but are more common in the cooler regions.

**Black Spruce Woodland Bog**: Stunted black spruce trees cover 25 to 60 percent of the ground over heath shrubs and sphagnum moss. Found in cold climate areas. These bogs are generally less than 50 acres in size in Vermont and are found in the cooler regions of Vermont, including the Southern Green Mountains.

**Pitch Pine Woodland Bog**: Pitch pine covers 25 to 60 percent of the ground over heath shrubs and sphagnum moss. This community is known only from Maquam Bog at the mouth of the Missisquoi River. Small patches of this community are scattered across this larger wetland matrix.

**Alpine Peatland**: This community has characteristics of both bog and poor fen, but is distinguished by its high elevation and the presence of particular plants. It is found only on the highest peaks of the Green Mountains, particularly Mount Mansfield. By their nature, these communities are limited in size to very small patches.

**Poor Fen**: These are open, acid peatlands dominated by sphagnum moss, sedges, and heath shrubs. There is some mineral enrichment of surface waters. Poor fens are scattered in all biophysical regions of Vermont.

**Intermediate Fen**: These open, slightly acid to neutral fens are dominated by tall sedges, non-sphagnum mosses, and a sparse to moderate cover of shrubs. Most examples are only several acres in size, with all known sites being less than 50 acres. These fens are found only in areas with calcium-rich bedrock, which may occur in all regions outside of the Green Mountains.

**Rich Fen**: These fens are similar to Intermediate Fen but typically have shallower sedge peat and more mineral-enriched surface waters. Sedges and non-sphagnum mosses dominate, and shrubs are present. All documented examples are 6 acres or less in size. Rich Fens are restricted to areas with calcium-rich bedrock in the Piedmont, Vermont Valley, and limited areas of the Taconic Mountains.
Open Peatlands Condition

Current Condition: Open peatlands occur in a variety of situations across the Vermont landscape, from small, hydrologically-isolated basins to components of large wetland matrices. The primary problems to SGCN in open peatlands include recreation, exotic species, hydrologic alterations, climate change, and habitat conversion and degradation. Peatlands are popular destinations for outdoor recreationalists interested in experiencing unique natural areas, an activity that can proved detrimental to these fragile communities and their associated SGCNs if not properly managed. Trampling of plants is a major concern especially near urban centers and at the more accessible sites. Nutrient enrichment of runoff waters due to agriculture can lead to invasion by exotic plants as well as replacement of rare plant species by more generalist species. The integrity of bogs and fens can be limited by significant changes in adjacent land use, such as development and clear-cutting, that result in increases in runoff and changes in water quality. Activities that alter the quality and quantity of water received from the groundwater recharge zone can be devastating to fen communities. Climate change is especially a concern with the Alpine Peatlands. Development of broadcasting facilities on mountain ridgelines also impacts this community type. Alteration of natural water level fluctuations in lakes, ponds, and streams associated with peatlands can also impact these wetlands. Prevention of natural disturbance regimes, including lightening-ignited fires, may limit the Pitch Pine Woodland Bog community.

Desired Condition (SGCN Needs): Many SGCN associated with this open peatlands, particularly some invertebrates and plants, are habitat specialists found only in these natural community types. Several SGCN dragonflies and damselflies require breeding and rearing habitat that is commonly described as bogs, fens, fen puddles, boggy ponds, boggy sloughs, and boggy streams. Many plants are found only in the wet, acid soils of bogs. Some vertebrates, such as bog lemmings (Synaptomys sp.) and spruce grouse are closely tied to bogs. Others, such as the blue-spotted salamander, four-toed salamander, spotted turtle, and water shrew, may rely on peatlands for habitat locally. Many of the other SGCN may utilize Open Peatlands but are not dependent on its specific characteristics (e.g., wood turtle, spruce grouse, and brown snake).

Marshes and Sedge Meadows Summary

Marshes and Sedge Meadows provide some of the largest natural openings to be found in Vermont. These natural communities and the streams and ponds with which they are associated provide critical habitat for many species of wildlife. Often called emergent marshes, these open wetlands have less than 25 percent shrub or tree cover, and in many cases woody plants are absent. Hydrology is the single most important factor controlling these wetlands.

Six different natural community types are included in this community type:

**Shallow Emergent Marsh**: This is a common and variable marsh type with mineral or shallow organic soils that are moist to saturated and only seasonally inundated. Several grasses, bulrushes, and Joe-pye weed may be abundant. This community is commonly associated with old beaver impoundments. This is a widespread natural community found throughout Vermont.

**Sedge Meadow**: These wetlands are permanently saturated and seasonally flooded. Soils are typically shallow organic muck, although mineral soils may be present in some wetlands. Tussock sedge or other sedges are dominant plants here. This common community is found throughout Vermont, most often along stream and pond margins and in beaver meadows.

**Cattail Marsh**: Common cattail or narrow-leaved cattail dominates these marshes. The muck or mineral soils are typically inundated with shallow standing water throughout the year, although the substrate may be exposed in dry years. Cattail Marshes range in size from less than an acre to over 500 acres along the shores of Lake Champlain. These common wetlands occur throughout the state but are most common at lower elevations.

**Deep Broadleaf Marsh**: Water depth in these marshes is typically over one foot deep for most of the year, although some may have only saturated soils in dry summers. Soils are organic. Common plants include pickerelweed, broad-leaved arrowhead, and giant bur-reed. This common community type is found throughout Vermont on the sheltered margins of lakes and ponds, on the slow-moving backwaters of larger rivers, and in isolated basins. The largest examples occur in lowland areas.

**Wild Rice Marsh**: These uncommon marshes are dominated by wild rice, with an organic soil substrate that is inundated with one to two feet of water throughout the summer. Wild Rice Marshes are found in wave-sheltered coves and on river deltas of Lake Memphremagog and Lake Champlain, and in the slow-moving backwaters of our larger rivers (Connecticut River and lower Champlain tributaries).

**Deep Bulrush Marsh**: These are marshes of open water along the shores of lakes and ponds. Water depths can range from one to six feet. Soft-stem bulrush and hard-stem bulrush dominate most of these marshes, although marsh spikerush and other bulrushes may be abundant. These common wetlands occur in open water along the shores of lakes and ponds and can be found throughout the state.

**Marshes & Sedge Meadows Condition**

**Current Condition**: These natural community types are not considered rare, but do provide critical habitat to many wildlife species, including SGCN. Sedge Meadows are often successional stages that would lead to forested wetlands if left undisturbed. Although they may occur in isolated basins, Marshes and Sedge Meadows are most commonly associated with water bodies...
(lakes, ponds, rivers) and other wetlands and, therefore, are subject to the same problems (e.g., pollution) as these associated communities. Many marshes, particularly Shallow Emergent Marshes, are small and not protected under Vermont Wetland Rules. Additional protection is needed for such wetlands important to SGCN through regulation and/or education. Invasive exotic species are a major problem for some of these community types. Common reed and purple loosestrife can easily become established in Shallow Emergent Marshes, and water chestnut can crowd out native species in Deep Broadleaf Marshes. Alteration of the natural hydrologic regime by dam operation or creation of impoundments can significantly impact deeper water communities. Greater inventory information is needed for all these natural community types as well as further study on the identification and significance of particular problems.

**Desired Condition (SGCN Needs):** Marshes and Sedge Meadows support a host of wildlife species. A variety of SGCN are marsh specialists. Among others, these include many plants, dragonflies, damselflies, butterflies, and birds. Several dragonflies and damselflies require breeding and rearing habitat that is commonly described as marshy ponds, marshy edges of lakes, and marshes. Black terns, least bitterns, and soras spend the nesting season raising their young within marshes. Some other SGCN, such as spotted salamanders, northern water snakes, and mink are commonly associated with these wetland types and may rely on them locally, but do not specifically require marshes to complete their life cycles. Pygmy shrews, smooth green snakes, and chimney swifts are examples of more casual users that may be found foraging in marshes and sedge meadows.

Wet Shores Summary

Characteristics and Distribution
All of the natural communities contained within the upland shore formation occur as small patches scattered irregularly over the landscape. Four of the natural communities are widely distributed while the three rarest types are restricted to one or more biophysical regions. All the community types in this formation are non-forested and maintained in this early successional state by a combination of flooding, ice scour, and erosional processes. This makes wetland shores perhaps our most dynamic and changeable group of natural communities.

The wet shores formation includes the seven following natural community types:

**Outwash plain pondshore:** This is among the rarest natural communities in the state and is found only in the Southern Vermont Piedmont Biophysical Region. It occurs only on sloping shorelines that are seasonally exposed due to fluctuating water levels. The vegetation is characterized by sedge, rush, and herbaceous species, many of them annuals.

**River mud shore:** This is a common natural community type that occurs in all eight biophysical regions. It is restricted to slow moving rivers whose shorelines are exposed during times of low flow. This community type tends to be sparsely vegetated, primarily by annuals since the shore is often exposed late in the growing season.

**River sand or gravel shore:** This is a common natural community type that occurs in all eight biophysical regions. It is restricted to the swifter rivers where moving water creates sand and gravel deposits. Because of their dynamic nature they are sparsely vegetated, mostly by grasses and herbs but often with a woody component consisting of willows and cottonwood.

**River cobble shore:** This common natural community is widely distributed across the state along high-energy waterways. Due to their dynamic nature, this community is sparsely vegetated, mostly by grass and sedge species, but often with a woody component of willows and cottonwood.

**Calcareous riverside seep:** This is a rare natural community type that is known mostly from the Connecticut Valley. They are restricted to areas where calcareous groundwater seeps on to exposed bedrock on rivershores. The natural processes of flooding and ice scour serve to keep the community open while the limy seepage sustains a unique flora that includes many rare species of sedges, herbs, and bryophytes.

**Rivershore grassland:** This is a widely distributed natural community that occurs in more sheltered, and hence more stable, portions of our larger rivers. Since the natural river processes needed to maintain their open condition occur less frequently, this community tends to have more of a woody component of shrubs and low trees mixed in with the more abundant grasses.

**Lakeshore grassland:** This rare natural community type is restricted to the shores of Lake Champlain and Lake Memphremagog where it occurs on gently sloping shorelines that are kept open by waves, flooding, and ice. They tend to be very narrow in width, but may extend for considerable distances along the shore. The community is dominated by grasses, sedges, and forbs with a varying amount of woody species depending upon the frequency and intensity of the natural disturbance.
**Wet Shores Condition**

**Current Condition:** All of the natural communities within the wet shore formation are dependent upon the natural processes of flooding, wave action, and ice scour. As such, they all occur as small patches that are restricted to areas where these processes are focused. Since they are maintained in an open state, all of these natural community types provide a specialized habitat for animals and plants. Spiny softshell, spotted, and wood turtles, Fowler’s toad, and tiger beetles all depend on one or more of these communities. Outwash plain pondshore and calcareous riverside seeps provide the unique habitat for plants and contain a disproportionate number of rare or Threatened species.

The primary problems to SGCN in this formation include hydrologic alteration, recreation, exotic species, and habitat conversion and degradation. Since all seven community types are dependent upon periodic disturbance by water, ice or wind, anything that prevents these natural processes from occurring would jeopardize the integrity and continued existence of the SGCN they harbor. These community types also support heavy recreational use, and trampling of vegetation is a major concern especially near urban centers and at the more accessible sites. The continual natural disturbance at these sites also provides excellent opportunity for invasive plants to become established, and recreational use adds to this potential. The river cobble shore and the two grassland types are especially subject to habitat conversion or degradation to create marinas, docks, and bathing beaches.

**Desired Conditions:** Although all the natural communities comprising the wet shore formation occur as small patches on the landscape, they all provide critical habitat to a number of SGCN that utilize both the aquatic and terrestrial environment or require unforested areas for basking, nesting, or foraging. A total of 22 animal and 31 plant SGCN are known to utilize the wet shore communities. To protect these sites we recommend the following activities:

**Species of Greatest Conservation Need in Wet Shores**

**High Priority**
- American Black Duck (Anas rubripes)
- Vesper Sparrow (Pooecetes gramineus)
- Spiny Softshell (Turtle) (Apalone spinifera)
- Fowler’s Toad (Bufo fowleri)
- Spotted Turtle (Clemmys guttata)
- Wood Turtle (Clemmys insculpta)
- Freshwater Snails group
- Tiger Beetles group
- Cobblestone Tiger Beetle (Cicindela marginipennis)
- Hoary Bat (Lasiurus cinereus)
- Eastern Pipistrelle (Pipistrellus subflavus)
- Water Shrew (Sorex palustris)

**Medium Priority**
- Blue-winged Teal (Anas discors)
- Red-shouldered Hawk (Buteo lineatus)
- Chimney Swift (Chaetura pelagica)
- Osprey (Pandion haliaetus)
- Pied-billed Grebe (Podilymbus podiceps)
- Lesser Yellowlegs (Tringa flavipes)
- Barn Owl (Tyto alba)
- Smooth Green Snake (Liochlorophis vernalis)
- Long-tailed Weasel (Mustela frenata)

**SGCN Notes:** Plant SGCN not listed here. The SGCN invertebrate groups listed here contain numerous species. For more information about a specific Species of Greatest Conservation Need see that species' assessment summary in Appendix A.

Shrub Swamps Summary

Characteristics and Distribution
All of Vermont’s shrub dominated natural communities are wetlands, and most are thought to be retained in this early successional state by periodic flooding. Some of the community types, however, are likely to be more transitional and will eventually become forested. These transitional types are believed to have arisen following some type of disturbance either natural, such as a catastrophic flood or beaver activity, or artificially from past agricultural use. If beaver activity and natural flooding are allowed to continue, examples of this community should continue to replace themselves on the landscape.

Of the four natural community types included within this formation two occur as small patches while the remaining two occupy larger areas on the landscape. Only one of the communities, buttonbush swamp, is thought to be rare in the state and restricted in its distribution to four of the state’s eight biophysical regions. The other three communities are distributed throughout the state.

The shrub swamp formation includes the following four natural community types:

**Alluvial Shrub Swamp:** This common natural community type is found on alluvial soils in the floodplains of small rivers. This is a high energy, dynamic environment that receives regular flooding and ice scour. As the stream channel naturally wanders across the floodplain, the community also migrates. Senescent channels succeed to floodplain forest while alluvial shrub swamps thrive in newly established channels. While speckled alder is the dominant species here, black willow and boxelder can be very abundant under certain conditions. Ostrich fern typically dominates the ground layer although some grasses, herbs, and vines can also be common in more sheltered areas.

**Alder Swamp:** This is a very common, widely distributed community type that occurs in a variety of settings including lakes and pond margins, backwater floodplains of rivers and streams, beaver flowerages, and poorly drained basins. Depending upon the frequency and duration of flooding, some examples may become more forested over time while others may remain shrub dominated. While speckled alder is the dominant shrub, shrubby willows, dogwoods, and young red maple may be locally abundant. Sedges and grasses along with sensitive fern and Joe pye weed typically dominate the ground layer.

**Sweet Gale Shoreline Swamp:** This relatively common natural community occupies shorelines of ponds and slow moving streams. This swamp typically occurs as a narrow floating mat, but the shrubs may also be rooted directly into the peaty shore. Sweet gale dominates this community, but speckled alder and meadow-sweet are usually also abundant. Leatherleaf may be co-dominant in more acidic, boggy conditions. Various sedge species typically dominate the ground layer.

**Buttonbush Swamp:** This relatively rare natural community occurs in two different settings: on the edges of larger lakes and ponds and in poorly drained, isolated depressions where water is retained through much of the growing season. Because of the permanently saturated conditions, this community typically occurs on deep, organic soils. While in some examples buttonbush may grow so dense that nearly all other vegetation is excluded, in other
situations leatherleaf and meadow-sweet may be common. Depending upon the shrub density and degree of flooding, various herbs and grasses may become established.

Shrub Swamps Condition

Current Condition: Shrub swamps are very common wetland types and occur in a variety of situations that are either too wet or too frequently disturbed to allow woody vegetation to become established. Although some examples are becoming forested, new examples continually arise due to natural disturbance. As long as the natural processes of flooding, ice scour, and beaver activity continue unabated, shrub swamps will remain common in our landscape.

The primary problems to the communities and SGCN in this formation include habitat alteration and fragmentation, suppression of the natural disturbance regime, hydrologic alteration, and invasive exotic species.

Desired Condition: Providing habitat for 30 SGCN makes shrub swamps among the more valuable community types for wildlife of concern is state. Especially notable is the high number of amphibians included in this total. There are few plant SGCN associated with shrub swamps, however; they provide habitat for only six vascular plants and three bryophytes. Many types of shrub swamps are commonly associated with larger wetland complexes along river and streams. Maintaining the natural flooding regimes and other natural processes including beaver activity of these shrub swamps and associated forested swamps and marshes is critical to their long-term function. Maintaining upland buffers for shrub swamps are especially important for amphibian SGCN as well as for other species.

Species of Greatest Conservation Need in Shrub Swamps

High Priority
- American Woodcock (Scolopax minor)
- American Black Duck (Anas rubripes)
- Black Tern (Chlidonias niger)
- Vesper Sparrow (Pooecetes gramineus)
- Spiny Softshell (Turtle) (Apalone spinifera)
- Fowler’s Toad (Bufo fowleri)
- Spotted Turtle (Clemmys guttata)
- Wood Turtle (Clemmys insculpta)
- Western (Striped) Chorus Frog (Pseudacris triseriata)
- Bog/fen/swamp/marshy pond Odonata group
- Freshwater Snails group
- Wetland Butterflies group
- Hoary Bat (Lasiurus cinereus)
- Water Shrew (Sorex palustris)

Medium Priority
- Blue-winged Teal (Anas discors)
- Red-shouldered Hawk (Buteo lineatus)
- Chimney Swift (Chaetura pelagica)
- Black-billed Cuckoo (Coccyzus erythropthalmus)
- Rusty Blackbird (Euphagus carolinus)
- Osprey (Pandion haliaetus)
- Pied-billed Grebe (Podilimbus podiceps)
- Lesser Yellowlegs (Tringa flavipes)
- Barn Owl (Tyto alba)
- Blue-spotted Salamander (Ambystoma laterale)
- Spotted Salamander (Ambystoma maculatum)
- Four-toed Salamander (Hemidactylium scutatum)
- Smooth Green Snake (Liochlorophis vernalis)
- Northern Water Snake (Nerodia sipedon)
- Common Musk Turtle (Stinkpot)
  (Sternotherus odoratus)
- Brown Snake (Storeria dekayi)
- Eastern Ribbon Snake (Thamnophis sauritus)

SGCN Notes: Plant SGCN not listed here: 9. The SGCN invertebrate groups listed here contain numerous species. For more information about a specific Species of Greatest Conservation Need see that species' assessment summary in Appendix A.

Upland Shores Summary

Characteristics and Distribution
All of the natural communities contained within the upland shore formation occur as small patches scattered irregularly over the landscape. Both the riparian associated natural communities occur in all eight biophysical regions of the state. In contrast, the three lakeshore natural communities are more restricted with both lake or shale cobble beach and sand dunes occurring in a single biophysical region and lake sand beach in three regions. Since all the upland shores are naturally kept open, all five natural community types provide specialized habitat for animals and plants. Riverside outcrops and sand dunes in particular provide habitat for some plants that occur nowhere else in the state. Generally SGCN have the best potential for persisting at sites with the most intact natural processes. These same sites likely provide the best and most abundant habitat for SGCN.

The upland shores formation includes the five following natural community types:

**Riverside outcrop:** This relatively common natural community occurs throughout the state wherever bedrock is exposed along waterways. They are dependent upon natural hydrologic processes that typically keep the sites open via either flooding or ice scour. This community type is sparsely vegetated, primarily by herbaceous species with only a few shrubs and vines able to withstand the regular disturbance regime.

**Erosional river bluff:** This is a rare natural community type with a statewide distribution that is restricted to steep banks where soil is actively eroding. Both the nature of the soils and the intensity of the erosional action greatly influences the vegetative cover of these communities, but rarely are woody species frequent.

**Lake or shale cobble beach:** This uncommon natural community can occur on any large lake in the state, but the only significant examples occur on Lake Champlain. Due to the constant wave action and seasonal flooding and ice scour, they tend to be sparsely vegetated. Although the vegetation is mostly herbaceous, willows, cottonwood, silver maple, and ash can become established at their upper reaches.

**Lake sand beach:** This is a rare natural community with the most extensive examples on the shore of Lake Champlain, and only scattered examples occurring in other regions of the state. Their formation and sustenance depends upon a regular source of material this is subsequently transported and deposited by waves and/or wind. Due to the constant wind and wave action and seasonal flooding and ice scour, this community is largely kept open. Typically herbs, grasses, and low sedges dominate although willows, cottonwood, box elder, and ash often becomes established at their higher reaches.

**Sand dune:** This extremely rare natural community is restricted to the present and previous shoreline of Lake Champlain where they are situated on the leeward side of sand beaches. They are dependent upon a continual supply of depositional sand and will be adversely affected by anything that inhibits this process. Because of the shifting nature of the substrate and the dry windy conditions, they are sparsely vegetated mostly by grasses, low sedges, and viney herbs. Cottonwoods, aspen, and gray birch eventually become established and make the dune system more stable.
Upland Shores Condition

Current Condition: All five community types within this formation are dependent upon continual disturbance by water, ice and wind and therefore occur in close proximity to lakes and rivers. They all reach their best development on the shores of Lake Champlain or other larger lakes and rivers in the state. Because they are desirable places to be, recreational use has impacted a number of our upland shores. The three lake associated shores are especially subject to habitat conversion or degradation to create marinas, docks, and bathing beaches. Trampling of plants is a major concern especially near urban centers and at the more accessible sites. The continual natural disturbance at these sites provides excellent opportunity for invasive plants to become established.

Desired Condition: Functional upland shores are primarily undeveloped sites where natural processes operate and human disturbance of SGCN is limited. Although all of the upland shores occur as small patches on the landscape, they provide a very specialized habitat that is utilized by a few SGCN and that may not be available elsewhere. Eight SGCN animals and one suite of species (tiger beetles) utilize upland shores. In addition, 33 SGCN plants are dependent upon this formation. To protect the natural communities contained within this formation we would do the following:

Outcrops & Upland Meadows Summary

Characteristics and Distribution
Outcrops and upland meadows are naturally unforested as a result of a number of factors: little or no soil, high winds, cold temperatures, and drought. Many of these factors are inter-related and work together in combination to limit tree growth. Outcrops and upland meadow are generally restricted to ridgetops and ledges where bedrock is exposed or close to the surface, and thus all the natural community types occur as small patches. They are often flat or gently sloping, but by definition, have slopes less than 60 degrees.

The outcrop and upland meadow formation includes the five following natural community types:

Alpine Meadows: This very rare natural community is restricted to the highest elevations in the state where the harsh growing conditions severely restrict vegetative growth. There are only a few known examples, all restricted to the Northern Green Mountains Biophysical Region. Low herbaceous vegetation, primarily grasses and sedges, dominate although stunted fir and black spruce and various heath shrubs occur in more sheltered locations.

Boreal Outcrop: This relatively common natural community occurs at mid to high elevations and is distributed widely in the cooler areas of the state. It occurs in the Northern and Southern Green Mountains, Northern Piedmont, Northeastern Highlands, and Taconics Biophysical Regions. They are sparsely vegetated by scattered low trees, including fir, red spruce, yellow birch, red maple, heath shrubs, and grasses. In some examples, however, mosses and lichens can be abundant and even dominate.

Serpentine Outcrop: One of the rarest natural communities in the state, serpentine outcrops are restricted to the Northern and Southern Green Mountains where this rock type is exposed. Serpentine rocks and the soils derived from them are very low in most plant nutrients, instead containing high amounts of heavy metals that can reach levels that are toxic to plants. The result is a sparse flora, but also one that has adapted to these extremely harsh conditions.

Temperate Acidic Outcrop: This is a relatively common natural community that is absent from only the higher elevations and colder regions of the state. Trees, especially paper and gray birch, white and pitch pine, and red maple are frequent here although they are stunted and slow growing. Beneath then typically grow low heath shrubs, grasses, and various herbs. Mosses and lichens can also be very abundant.

Temperate Calcareous Outcrop: This is an uncommon natural community that is restricted to the warmer regions of the state; generally the Champlain and Connecticut River Valleys, the Taconics and the Vermont Valley. The community is limited to areas with calcareous bedrock and thus support a characteristic flora of lime-loving plants. Despite their exposure and resulting droughtiness, the availability of nutrients makes these outcrops more diverse than their more acidic counterparts.
Outcrops & Upland Meadows Condition

Current Condition: All of the natural communities contained within the outcrop and upland meadow formation are the result of specific conditions, and as such, they occur as small patches and are scattered irregularly over the landscape. Only temperate acidic outcrops occur in all eight biophysical regions of the state. In contrast, alpine meadows are restricted to a single biophysical region and serpentine outcrops to two regions. Since they all are open communities within a generally forested matrix, all five natural community types provide a specialized habitat for animals and plants. They are important basking sites for reptiles, and alpine meadows, serpentine outcrops, and temperate acidic outcrops in particular provide habitat for many plants that occur nowhere else in the state.

The primary problems to SGCN in this category include recreation, exotic species, climate change, and habitat conversion and degradation. Since all five community types provide vistas, they are often a destination for hikes, skiers, and climbers. Trampling of plants is a major concern especially near urban centers and at the more accessible sites. Invasion by exotic plants, especially at the lower elevation temperate outcrops and all communities with major trail access, is increasingly a concern. Alpine meadows are affected by ski area development while both serpentine and temperate calcareous outcrops continue to be limited by mining operations. Climate change is especially a concern with the colder alpine meadows and boreal outcrops.

Desired Condition: Outcrops and upland meadows are very specialized natural communities in Vermont since they are relatively permanent openings within a forested landscape. As such they provide specific habitat requirements for a small number of SGCN, especially some species of snakes which utilize these openings as basking sites. Although they provide significant habitat for only nine SGCN and two suites of species (moths and tiger beetles), these openings are utilized by many additional wildlife species. The number of SGCN plants (95) that rely on this formation speaks to its importance in the state despite the small area that it covers. To protect these sites we would do the following:

SGCN in Outcrops & Upland Meadows

High Priority
- Eastern Racer (Coluber constrictor)
- Timber Rattlesnake (Crotalus horridus)
- Eastern Rat Snake (Elaphe obsoleta)
- Moths group
- Tiger Beetles group
- Northern bog lemming (Synaptomys borealis)
- Southern Bog Lemming (Synaptomys cooperi)

Medium Priority
- Chimney Swift (Chaetura pelagica)
- Osprey (Pandion haliaetus)
- Cinereus or Masked Shrew (Sorex cinereus)
- Smoky Shrew (Sorex fumeux)

Cliff & Talus Summary

Characteristics and location
Cliffs are areas of exposed bedrock, with slopes greater than 60 degrees. Examples range from very small and shaded by surrounding forests to extensive sites greater than one hundred acres. Vermont’s cliffs are divided on the basis of their climatic affinities and their bedrock. Climate is the factor separating boreal cliff types from temperate cliff types. The boreal types are found in the cooler regions of the state, the Northeast Highlands and the Green Mountains, though a few are found in generally warmer regions, in especially cool situations such as at high elevations or in cold valleys. The temperate types are found either at middle to low elevations or in the warmer regions of the state. Bedrock is the factor separating acidic cliff communities from calcareous cliff communities. Granites, some quartzites, and sandstones are typically acidic, whereas limestones, dolomites, calcareous schists, and some quartzites are calcareous. [Thompson and Sorenson 2000]

Talus slopes are areas of rockfall below cliffs and are characterized by an accumulation of many rocks broken off a cliff face through physical forces including freezing and thawing.

Types of Cliff and Talus Communities:

**Boreal Acidic Cliff:** These are high elevation cliffs, generally above 2,000 feet, found on acidic bedrock such as granite, gneiss, quartzite, or non-calcareous schist. Vegetation is usually red spruce, balsam fir, American mountain-ash, bush-honeysuckle, three-toothed cinquefoil, and hairgrass. Eastern Hemlock is absent from these cliffs. Found primarily in the cooler regions of the state, the Northeast Highlands and the Green Mountains.

**Boreal Calcareous Cliff:** These are high elevation cliffs, mostly above 2,000 feet, where calcareous bedrock (usually calcareous schist, but occasionally limestone or marble) combined with seepage creates conditions that favor certain calciphilic plants, some of which are quite rare statewide.

**Temperate Acidic Cliff:** These are lower elevation cliffs, generally below 2,000 feet, found on acidic bedrock. Characteristic vegetation includes eastern hemlock, white pine, red maple, paper birch, harebell, and heart-leaved aster. Found primarily either at middle to low elevations or in the warmer regions of the state.

**Temperate Calcareous Cliff:** These are low elevation cliffs in warmer areas on limestone, marble, dolomite, or calcareous quartzite. They may be moist or dry, depending on the situation, but usually do not have abundant seepage. Some characteristic species are northern white cedar, purple clematis, smooth cliff-brake, purple-stemmed cliff brake, harebell, and herb robert. Found primarily either at middle to low elevations or in the warmer regions of the state.

**Open Talus:** This broadly defined community type includes all areas of open rockfall. These rockfall areas usually occur below cliffs, and can be comprised of granite, quartzite, gneiss, shale, or less commonly limestone or marble.
Cliff & Talus Condition

Current Condition: Generally, cliffs and talus communities are not directly vulnerable to habitat degradation simply because they tend to be inaccessible and limited in timber or development potential. Recreational activities and intensive quarrying may be the greatest impacts to these communities where such activities occur.

Desired Condition (SGCN Needs): Cliffs and talus are often host to habitat specialists, many of which are plants directly linked to the natural community type. In general, the larger the site, the greater the likelihood that numerous SGCN plant species will exist and that they will persist. Many of the animal species associated with this community types; however, do require accessible, unfragmented habitat mosaics. Several of the animal species require the cliff and talus for nesting or hibernation, but range as far as 1000 ha from the site. Three of the species (eastern racer, rock vole, and five-lined skink) specifically benefit from active management for early successional features or small openings around the sites in order to provide solar radiation. The eastern racer is found on only one site in Vermont. The five cliff and talus community types provides the habitat for 100 SGCN.

Lake Champlain Tributaries Summary

These waters include the lower-most portions of tributaries that empty into Lake Champlain. On many rivers and streams this is defined at its upstream end by the first major waterfall or cascade, called the principal fall line. On streams which do not have this abrupt elevation change, the upstream limit for is roughly 150 feet above sea level. The SGCN supported in these waters are numerous, with many found nowhere else in the state but in here and Lake Champlain. There are several factors accounting for the unique aquatic assemblages found here, including: glacial history and ancient routes of colonization from the west and south; the barrier to upstream migration presented by the principal fall line; and the generally warmer temperatures and finer substrates found here compared to those in higher elevation areas of Vermont. Unique species include many fishes and freshwater mussels, the common mudpuppy, and the spiny softshell. Key features include riffles, runs, and long pools with a variety of dominant substrate types. Small gravel, sand, and finer substrates are more dominant in the lowest reaches of these streams and rivers. Woody debris is prevalent, especially in deep holes in pool sections.

Lake Champlain Tributaries Condition

Current Condition: Some of the most heavily human-populated areas of the state occur adjacent to river sections included in this community type. While the larger volumes of water carried by the large rivers in Lake Champlain tributaries do afford a greater diluting potential than found in smaller rivers and streams, these Champlain tributaries are located in an area of the state where the intensity and frequency of insult to the aquatic habitat from human use is expected to be greater. For example, stormwater runoff reaching the lower Winooski River from developed lands is much greater than in most other Vermont fluvial communities. Stormwater runoff from developed lands increases the amount of sediments, nutrients, and contaminants that reach rivers instead of being trapped by the soil and vegetation. Floodplains function, in part, to absorb runoff and deliver it slowly to rivers through the soil. Paving of land sends water more directly to streams and rivers, in essence bypassing the floodplain. This creates a scouring effect on riverine habitat, due to the more extreme fluctuations in velocity of stormwater runoff.

Pollutants enter these rivers from various non-point sources as well. Agricultural lands located adjacent to rivers within these watersheds can contribute excessive amounts of silt, nutrients, and pesticides to the systems when adequate riparian buffers are not maintained. In such instances, excessive sediments can cover coarser river-bottom substrates needed by many SGCN, as well as covering some of these species themselves. Also, salt from roadways makes its way into rivers, degrading the water quality. These and other sources of non-point pollution are likely the greatest contributors of contaminants to these systems. These pollutants comes not only from adjacent lands, but from the entire watershed.

Accidental contaminant spills are rare, but can have immediate and devastating effects on the aquatic environment and the SGCN that live there. Chemicals, manure, industrial waste, and other potential contaminants stored in areas where they could reach these rivers or their tributaries if released are significant problems. Bridges and riverside roads and railways also present long stretches where accidental spills into rivers and streams can occur. A catastrophic contaminant spill could (and has) easily wipe out entire SGCN populations. As with other sources of pollution, this problem comes from the watershed upstream as well as adjacent lands.
Direct loss of habitat occurs when fill material is placed on the river bottom. Examples of this include riprapping to stop toe erosion along streambanks, placement of piers or causeways to accommodate bridges, and construction of boating access facilities. Direct mortality of freshwater mussels, which live on the river bottom, is sometimes the result of these activities within lower Champlain rivers. The replacement of natural substrates with large stone provides reduced or unsuitable habitat for recolonization by bottom-dwelling animals. The construction of buildings and roads adjacent to rivers creates a hazard for the structures, increasing the potential that bank stabilization will be pursued.

Two dams on major rivers within the Lake Champlain tributaries have cut off migration for fishes and mussels, and have resulted in the loss of spawning habitat for some species. Impoundments created by these structures have altered the natural habitat from riverine to more lake-like water bodies. “De-watering” of the aquatic habitat that sometimes occurs due to atypical “hydro-peaking” dam operations leaves many benthic SGCN, particularly mussels, out of the water and exposed to the elements and predators. This can occur upstream or downstream of these structures. Existing dams located on fall lines may significantly alter the natural physicochemical regime of waters flowing downstream. The altered hydrologic regimes found below dams degrades the quality of habitat here for SGCN.

Zebra mussels that have devastated the Lake Champlain freshwater mussel community are a problem for rivers in this Lake Champlain tributaries. Adult zebra mussels have been found in the lower reaches of Otter Creek, Little Otter Creek, Lewis Creek, LaPlatte River and the Winooski River in past years. They are also present in Lake Bomoseen, whose outlet stream feeds into the Poulney River.

**Desired Condition (SGCN Needs):** These waters, along with Lake Champlain, support the greatest diversity of aquatic species found in the state. The larger rivers support the highest number of SGCN. Species include both year-round residents and those that use the rivers and streams primarily for spawning, development of young, or feeding. Minnows, freshwater mussels and snails, benthic fishes, and mammals are among those that utilize the Lake Champlain tributaries year-round, and often require a variety of habitats. Lake sturgeon, mooneye, greater redhorse, and possibly common mudpuppy are among those that depend on these rivers seasonally for reproduction. Others, such as map turtle, spiny softshell, northern watersnake, wood turtle, and bats use these waters for foraging, winter shelter, or other seasonal purposes.

Gravel/cobble substrates that are free of loose silt are required by many of the riverine species that spawn here. Eggs in contact with excessive silt are not able to adequately absorb oxygen for development. The eastern sand darter requires silt-free sand for this purpose. Substrates also need to be stable in order to support many SGCN, particular benthic organisms like freshwater mussels, darters, hibernating spiny softshells, and nesting mudpuppies. This is often affected by stream hydrodynamics; that is, streams that are hydrodynamically imbalanced can have substrates that shift frequently and do not provide a firm footing or shelter for aquatic organisms that occur there. Small invertebrates are less abundant in silted-in or unstable stream bottoms, thus providing a reduced food source for their predators. Woody debris is an important habitat component in lower Lake Champlain tributaries, especially for aquatic insects. Historically, people removed trees and branches that fell into streams. Unfortunately, this removed the structure and habitat needed for many invertebrates and their predators, as well as basking habitat for turtles.
Two aquatic SGCN, the American eel and the Atlantic salmon, were historically able to ascend the fall line from downstream. The American eel did so to reach smaller waters upstream where the young eels would grow for several years before migrating back out to sea to spawn. Landlocked Atlantic salmon jumped the falls to reach the clean, coarse gravel substrates located upstream where they would spawn their eggs. With the construction of dams at or below the falls on all the major Lake Champlain rivers, much of the habitat needed for these two species was made unavailable to them. Reconnection of these fishes with this habitat would likely be beneficial to their long-term survival.

River otter and mink are susceptible to heavy metals and PCB's.

Lower Connecticut River Summary

Characteristics and Location
The Lower Connecticut River encompasses approximately 130 miles of the main stem from the Massachusetts state line upstream to its confluence with the Wells River and occurs almost exclusively within the Southern Vermont Piedmont biophysical region. Additionally, this summary includes the lower sections of its Vermont tributaries that are directly influenced by or have physical and/or biological similarity to the Connecticut River. The presence of a readily identifiable geological feature, such as a fall line, is not evident on all tributaries. Where the fall line is apparent, typically within a short distance from the tributary mouth (e.g., as on the Williams, Black, Ottauquechee, Waits and Wells rivers), this feature delineates the upstream extent of the Lower Connecticut River. On other tributaries (e.g., the West and White rivers), artificial structures (e.g., the lowermost dam) are used to define the upstream limit. Rivers and streams located within the Connecticut River basin but upstream of the habitat boundary are covered under the Fluvial (Stream) Summary. To a limited degree the historic distribution of several anadromous fish species native to the Connecticut River basin, namely sea-run Atlantic salmon, American shad and sea lamprey, as well as current management goals for the restoration of these fishes to the basin also define the bounds of the Lower Connecticut River.

Lower Connecticut River Condition
Current Condition: Prior to European settlement and subsequent industrial development of the Connecticut River basin, rivers and streams were free-flowing systems subject to natural flow regimes and processes. Waters ran free of pollutants, and the landscape, including riparian lands, was predominantly forested. These conditions provided habitat for both aquatic and terrestrial plant and wildlife assemblages native to the Lower Connecticut River. However, over the past 200 plus years, the river and its tributaries have been altered extensively fragmenting historic migration routes, changing natural habitats and ecological functions, as well as the current composition of the plant and wildlife communities.

Dams constructed for waterpower and flood control have greatly altered river and streams throughout the Connecticut River basin. Historic migration corridors used by Atlantic salmon, American shad, blueback herring, sea lamprey and American eel to gain access to critical spawning and nursery habitats have been obstructed. Long sections of the main stem and tributaries have been transformed from free-flowing waters to impoundments; and natural flow regimes are now regulated in ways that are not compatible with the habitat requirements of many aquatic species, including SGCN. Impoundments and artificial flow regimes have significantly influenced sediment transport and deposition, which in turn have altered the character, quantity and quality of various habitat types found throughout the Lower Connecticut River. Waters above and below dams are managed in ways, which result in fluctuating impoundment levels and tail water discharges. Frequently, flows released from dams are not adequate in volume or fluctuate in magnitude and duration so as to create habitat conditions unsuitable for SGCN. While water management within impoundments and free-flowing river segments may benefit habitat for a few SGCN (e.g., expose mudflats and shorelines used by feeding lesser yellowlegs during migration), fluctuating water levels can be detrimental to strictly aquatic SGCN (e.g., redbreast sunfish, common mudpuppy).
The extensive conversion of the Connecticut River from a free-flowing system to one
-dominated by impoundments has created habitats suitable to a variety of aquatic exotic
plants and animals. Shorelines and wetlands associated with these impoundments have been
invaded by phragmites, Eurasian milfoil and purple loosestrife, which have established
dominant stands degrading nesting habitats needed by waterfowl, songbirds and muskrats. In
recent years water chestnut was discovered in North Springfield Reservoir, which is on the
Black River, a tributary of the Connecticut River. It has also been found in sections of the
river in Massachusetts and Connecticut. This invasive exotic aquatic plant has been a
significant environmental problem on Lake Champlain demanding large expenditure of
funds and labor to keep it under control. Several fish species not indigenous to the
Connecticut River, including predatory largemouth bass, northern pike, bluegill, crappie and
rock bass, were introduced during the 1800s and early 1900s and have benefited from habitat
formed within the impoundments. These species have altered the composition of the natural
fish community of the river and have influenced ecological relationships at all trophic levels.
At the present time, zebra mussels have not been found in the Connecticut River.

Prior to the federal Clean Water Act (amended in 1977) and subsequent implementation of
water pollution abatement programs, a 1951 government report described the Connecticut
River as the “best landscaped sewer in New England” (CRJC 1997). Over the past three
decades water quality in the river and its tributaries has vastly improved habitats for aquatic
SGCN. Nonetheless these waters continue to receive point and non-point source pollution
(sediments, nutrients, toxic chemicals), which remain problems to aquatic habitats and the
ability of the environment to support healthy, sustainable populations of SGCN, such as
eagles, ospreys, fishes, freshwater mussels, and other aquatic invertebrates. Healthy aquatic
systems are important to maintaining food webs not only for aquatic SGCN but also
terrestrial species (eagles, ospreys, bats, otter, mink).

Development and logging along the river and tributaries has had a significant impact on
riparian areas functions and benefits to SGCN. The loss of naturally vegetated (forested)
riparian areas have lead to increased inputs of sediment and other pollutants to streams,
increased water temperatures, channel instability, and loss of in-stream habitat structure
created by the recruitment of large wood. Removal of living and dead trees (snags) from
riparian lands has reduced sites for eagle and osprey nesting, roosting and perching.

Unique to the Lower Connecticut River is the existence of the Vermont Yankee Nuclear
Power Station, which uses the river as a source of reactor cooling water and by state permit
is allowed to discharges waste heat within specified thermal limits to the river. Excessive heat
discharged to the river can potentially limit the temperature regime of the river within
vicinity of the power plant to the detriment of aquatic SGCN intolerant of warm water. On a
larger scale is the effect of climate change on aquatic habitats critical to certain SGCN (e.g.,
Atlantic salmon, American eel).

Desired Conditions (SGCN Needs): Eventual restoration and maintenance of sustainable
populations of migratory native fishes to the Connecticut River basin is dependent on
eliminating or mitigating artificial barriers which currently do not allow fish access to critical
habitats, whether freshwater spawning and nursery areas or seawater (e.g. Atlantic salmon,
American shad, sea lamprey, American eel). Dam removal would open river migration
corridors, as well as restore natural flow regimes, sediment transport and other fluvial
processes essential to creating and maintaining instream aquatic habitat. Where dam removal is not feasible, fish passage should be restored by retrofitting structures with fish ladders, lifts or similar devices. Existing fishways demand continued operation and maintenance to assure their effectiveness. New dam construction should be avoided. Establishing flow regimes below dams and water level management within impoundments that mimic natural systems would benefit many of the aquatic SGCN.

The reduction of sediment inputs to the Lower Connecticut River from land development and chronic streambank erosion is important to maintaining SGCN populations, many of which depend on habitats consisting of coarse river bottom substrates (i.e., gravels and cobbles) that are not embedded by finer substrates. Riparian vegetation contributes to the reduction of these fine sediment inputs to surface waters by obstructing and slowing down overland runoff, while also reinforcing streambanks against the erosional forces of running water. Riparian areas also provide several habitat functions for species that inhabit them. Mature trees in the riparian zone provide necessary nesting sites for eagles and ospreys. These trees eventually may be recruited to the river channel, creating instream habitat such as refuge cover required by common mudpuppy and redbreast sunfish.

The potential for new non-indigenous invasive organisms (e.g., zebra mussel, Asiatic clam, hydrilla) becoming established in the Connecticut River is a persistent problem for the native biota and habitats.

### Species of Greatest Conservation Need in Lower Connecticut River

#### High Priority
- Peregrine Falcon (*Falco peregrinus*)
- Bald Eagle (*Haliaeetus leucocephalus*)
- American Eel (*Anguilla rostrata*)
- Anadromous Atlantic Salmon (*Salmo salar*)
- Common Mudpuppy (*Necturus maculosus*)
- Freshwater mussels group
- River/stream Odonata group
- Silver-haired Bat (*Lasionycteris noctivagans*)
- Eastern Red Bat (*Lasiurus borealis*)
- Hoary Bat (*Lasiurus cinereus*)
- Eastern Pipistrelle (*Pipistrellus subflavus*)

#### Medium Priority
- Blue-winged Teal (*Anas discors*)
- Osprey (*Pandion haliaetus*)
- Pied-billed Grebe (*Podilymbus podiceps*)
- Lesser Yellowlegs (*Tringa flavipes*)
- Blueback Herring (*Alosa aestivalis*)
- American Shad (*Alosa sapidissima*)
- Redbreast Sunfish (*Lepomis auritus*)
- Sea Lamprey (*Petromyzon marinus*)
- Northern River Otter (*Lutra canadensis*)
- Mink (*Mustela vison*)
- Muskrat (*Ondatra zibethicus*)
- Cinereus or Masked Shrew (*Sorex cinereus*)

#### SGCN Note:
The SGCN invertebrate groups listed here contain numerous species. For more information about a specific Species of Greatest Conservation Need see that species' assessment summary in Appendix A.
### Problems & Information Needs

Lake Champlain Summary

Lake Champlain includes the main body of the lake and its bays and river deltas. These waters are shared with New York and Quebec. At about 120 miles in length and a maximum depth over 400 feet, this is Vermont’s largest waterbody. Aquatic habitats found here are many and extensive. Among these are expansive sand-bottomed shallows, shale/cobble littoral shorelines and bays, and deep limnetic environments. Other natural communities, such as large tributaries, emergent marshes, and floodplain forests, are integral to Lake Champlain and provide a critical habitat component for many SGCN found here. This is, in general, an oligo-mesotrophic lake, with nutrient levels in different parts of the lake dependent on local soil and bedrock types, as well as the type and extent of human land use within the surrounding watershed. This lake supports the highest lacustrine diversity of any of our lakes, which is due mainly to its large size and connections (current and historical) with the Great Lakes-St. Lawrence River and the Hudson River.

Lake Champlain Condition

Current Condition: The most outstanding concerns facing this large system are water quality and habitat degradation, and invasive exotic species. The lake is within the largest watershed in Vermont and is fed by many large tributaries that drain extensive agricultural and developed lands. A significant portion of the excessive nutrients, contaminants, and fine sediments that enter streams and rivers eventually reach Lake Champlain. Water and benthic habitat quality are affected, particularly in delta areas and along the shoreline, but also within the open and deeper waters over time. SGCN that are sensitive to contaminants and those that depend on consolidated (firmly-packed) substrates may be impacted by these changes to their habitat. Development along Lake Champlain’s shoreline and within smaller watersheds immediate to the lake is ever-increasing, and with it the amount of contaminants entering directly into the lake. Excessive nutrients that reach the lake from various land uses within the watershed can cause eutrophication, reducing water quality and altering food webs. Zebra mussels have had a dramatic and devastating impact on the biotic community of Lake Champlain, including populations of many SGCN. These exotic pests foul the shells of native freshwater mussels, decreasing their ability to move about and obtain food and oxygen, resulting in a slow death. Populations of native mussels have been eliminated from large areas, a scenario that has repeated itself throughout most of the lake. The only areas where native mussels have not been seriously impacted by zebra mussels are Mallets Bay, the Inland Sea, and Missisquoi Bay. Water chestnut is an invasive that has impacted aquatic communities in the lake by forming huge, dense masses that cover the water surface and crowd out species. The exotic snail *Bithynia tentaculata* now dominates much of the shale/cobble habitat in Lake Champlain, likely reducing native snail populations and altering the food web. Among other invasive exotics that loom on the horizon for Lake Champlain are round goby, alewife, quagga mussel, and rusty crayfish. Additional problems to Lake Champlain include habitat conversion and vulnerability to catastrophic contaminant spills.

Desired Condition (SGCN Needs): These waters, along with Lake Champlain tributaries, support the greatest diversity of aquatic species found in the state. SGCN supported by Lake Champlain include mid- to deep-water species like cisco and lake whitefish that require cold, well-oxygenated waters. Shallow-water species such as mooneye and sauger utilize upper portions of the lake where temperatures are often much warmer. Near-shore and benthic species like bridle shiner, pink heelsplitter, giant floater, and spiny softshell are often found in bays or in the shallows of deltas.
The lake offers a variety of habitats that provide for the many needs of aquatic species, such as refuge, food, thermal protection, and spawning substrate. The great majority of freshwater mussel species remain buried in the substrate most of their lives, where they grow, feed, produce offspring, and seek refuge from the elements. Lake sturgeon feed on lake-bottom invertebrates, only entering rivers for brief periods to spawn. Different fishes can be found occupying different strata of the lake where they find the temperatures and oxygen levels they prefer. Degradation of water quality through nutrient input, thermal shifts, or other changes can cause significant alterations in food webs and habitat availability. Similarly, excessive fine sediments entering the lake from the shoreline and tributaries blankets and degrades the benthic substrate used by many SGCN. Improvement and protection of Lake Champlain’s water quality, including reduction of nutrient and fine sediment inputs, is paramount to ensure that the SGCN populations found here remain viable. Control of exotic species, including preventing new species from invading, is also of great importance to the survival of these native species.

Many SGCN utilizing Lake Champlain depend on closely associated aquatic, wetland, and terrestrial habitats to complete their life cycles. Many fish, such as lake sturgeon, greater redhorse, and mooneye are found in the lake most of the year, but spawn over rocky substrates in Champlain tributaries. Osprey feed in the lake but need nearby suitable nesting trees or structures to raise their young. Spiny softshells occupy the lake much of the year for basking, feeding, and over-wintering, but require adjacent beaches of sand or gravel/cobble for egg-laying. Bats feed on emerging aquatic insects over the lake, while utilizing upland roosting and nursery sites. Muskrats river otter and mink find a rich aquatic food source within Lake Champlain and its associated wetlands, but must den above the waterline. Maintaining these connections to critical wetland, aquatic, and terrestrial habitat is key to ensuring the continuation of these SGCN in the lake.

Species of Greatest Conservation Need in Lake Champlain

**High Priority**

- Peregrine Falcon (Falco peregrinus)
- Bald Eagle (Haliaeetus leucocephalus)
- American Brook Lamprey (Lampetra appendix)
- Lake Sturgeon (Acipenser fulvescens)
- American Eel (Anguilla rostrata)
- Muskellunge (Esox masquinongy)
- Silver Redhorse (Moxostoma anisurum)
- Greater Redhorse (Moxostoma valenciennesi)
- Quillback (Carpiodes cyprinus)
- Sauger (Sander canadense)
- Blackchin Shiner (Notropis heterodon)
- Bridle Shiner (Notropis bifrenatus)
- Crustaceans Group
- Freshwater Mussels Group
- Freshwater Snails group
- Spiny Softshell (Apalone spinifera)
- Silver-haired Bat (Lasionycteris noctivagans)
- Eastern Red Bat (Lasiurus borealis)
- Hoary Bat (Lasiurus cinereus)
- Eastern Pipistrelle (Pipistrellus subflavus)

**Medium Priority**

- Osprey (Pandion haliaetus)
- Cisco or Lake Herring (Coregonus artedi)
- Lake Whitefish (Coregonus clupeaformis)
- Mooneye (Hiodon tergisus)
- Silver Lamprey (Ichthyomyzon unicuspis)
- Shorthead Redhorse (Moxostoma macrolepidotum)
- Atlantic Salmon (landlocked) (Salmo salar)
- Lake Trout (naturally reproducing populations) (Salvelinus namaycush)
- Mink (Mustela vison)
- Muskrat (Ondatra zibethicus)
- Northern River Otter (Lutra canadensis)

**SGCN Note:** SGCN plants not listed here 7 species. The SGCN invertebrate groups listed here contain numerous species. Sea lamprey is not a Species of Greatest Conservation Need.
in the Lake Champlain Basin. For more information about a specific Species of Greatest Conservation Need see that species' assessment summary in Appendix A.

Lacustrine Summary (excluding Lake Champlain)

Characteristics and Location
Lacustrine areas include natural lakes and ponds throughout Vermont, which can be classified on the basis of their productivity and associated physio-chemical characteristics. Lake types discussed here include oligotrophic lakes, mesotrophic lakes, eutrophic lakes, high elevation acidic lakes, and dystrophic lakes. Lake Champlain, representing oligotrophic, mesotrophic and eutrophic habitat types, is not included in this summary due to its large size and unique species assemblages (see Lake Champlain Summary). The following descriptions of Vermont lake types are based in part on parameters provided by the Vermont Department of Environmental Conservation, Water Quality Division, Lakes and Ponds Section.

Types of Lacustrine Communities:

**Oligotrophic Lakes:** These lakes are typically deep with clear, cold water; low in dissolved nutrients, such as phosphorus and nitrogen; and experience seasonal periods of temperature and oxygen stratification and de-stratification (mixing). Biochemical parameters generally characterizing this lake type are: (1) total phosphorus concentration in the summer photic zone, <10 µg/L; total nitrogen concentration, <0.35 mg/L; average summer chlorophyll-a concentration, ≤3.5 µg/L; and average summer secchi disc depth, ≥5.5 m. Another general feature of oligotrophic lakes is the lack of an extensive littoral zone. Littoral plants are scarce and plankton density is low. Several SGCN uniquely associated with this lacustrine waters are landlocked Atlantic salmon, lake trout, and round whitefish. In Vermont, lakes of this type are predominantly located in the Northeast Highlands biophysical region.

**Mesotrophic Lakes:** Lakes of this type are intermediary between oligotrophic (nutrient poor) and eutrophic (nutrient rich) systems. Mesotrophic lakes are shallower than oligotrophic lakes, have a well-established littoral zone supporting aquatic vegetation, and are moderately rich in dissolved nutrients. Consequently, primary productivity and plankton densities are greater than in oligotrophic systems but less than in eutrophic waters. Biochemical parameters generally characterizing this lake type are: (1) total phosphorus concentration in the summer photic zone, 10 to 24 µg/L; total nitrogen concentration, 0.35 to <0.65 mg/L; average summer chlorophyll-a concentration, >3.5 to 7.0 µg/L; and average summer secchi disc depth, 3.0 to 5.5 m. Several SGCN uniquely associated with meso-eutrophic lakes are bridle shiner, blackchin shiner, redbreast sunfish, common musk turtle, and northern water snake. Lakes of this type are distributed throughout Vermont; however, those supporting one or more populations of SGCN tend to be represented in greater frequency in the Champlain Valley and Connecticut River biophysical regions.

**Eutrophic Lakes:** Lakes of this type are generally characterized as nutrient mature systems. They are richer in dissolved nutrients and generally shallower than oligotrophic and mesotrophic lakes with extensive littoral areas supporting prolific growths of aquatic vegetation. Primary productivity and plankton densities are greater than in mesotrophic lakes. Eutrophic lakes that thermally stratify are likely to experience oxygen depletion below the thermocline during summer and/or winter stratification periods. Oxygen depletion during winter can occur when ice cover prohibits atmospheric exchange of oxygen resulting in “winter-kill” conditions. Biochemical parameters generally characterizing this lake type are: (1) total phosphorus concentration in the summer photic zone, >24 µg/L; total nitrogen concentration, >0.65 mg/L;
average summer chlorophyll-a concentration, ≥7.0 µg/L; and average summer secchi disc depth, 0 to 3.0 m. SGCN associated with eutrophic lakes are similar to mesotrophic lakes with decreasing occurrence in lakes of more advanced eutrophication. Though advanced eutrophication may make unsuitable habitat for purely aquatic SGCN, the productivity of these waters may be important to terrestrial and semi-aquatic species (e.g., bald eagle, osprey, bats and northern water snake) due to the abundance of food organisms these waters are capable of producing. Lakes of this type are distributed throughout Vermont but are more likely to be at low elevations and in disturbed landscapes.

**High Elevation Acidic Lakes:** These are clear-water lakes generally located at elevations over 1500 feet with neutralizing capacity (ANC) less than 25 mg/L and more typically within the range of 0 to 5 mg/L. Lakes of this type are vulnerable to and in some cases are known to be adversely affected by acid deposition. These lakes are usually small and shallow, with rocky or gravelly bottoms, and little accumulated organic material. Dissolved nutrient concentrations and primary production are generally low. Relatively few SGCN are associated with high elevation acidic lakes. One possible associate is brook trout. In Vermont lakes of this type are generally distributed within the Northern and Southern Green Mountain biophysical regions.

**Dystrophic Lakes:** Lakes of this type are usually associated with bogs. These are characterized by brown stained water (color >50 Pt Co) and are high in nutrients and humic materials. Dystrophic lakes are often acidic and may be anoxic or nearly so in the deeper waters. Relatively few SGCN are associated with dystrophic lakes with the possible exception of brook trout. Although examples of dystrophic lakes may be found statewide, generally they are more abundant in the Northern Green Mountains, Southern Green Mountains and Northeast Highlands biophysical regions.

**Lacustrine Condition**

**Current Condition:** The lacustrine (lake) waters represented in this summary have notably different physio-chemical characteristics, therefore problems and changes to their water quality and chemistry may affect each lake type and species assemblages in different ways. Most oligotrophic and mesotrophic lakes in Vermont have experienced abundant lakeshore development, both historically and currently, such as seasonal and permanent residences, marinas and docks, and public and private beaches. In many instances these developments have altered natural lakeshore and littoral habitats through the addition of fill materials (e.g., sand, bottom barriers), removal of large woody debris, and removal of native aquatic vegetation for beach construction and maintenance, resulting in the direct loss of habitats for SGCN. Additionally, development has increased stormwater runoff to lakes and has elevated the input of pollutants, including sediments, nutrients, and toxic chemicals. Nutrient loading can accelerate the eutrophication process causing excessive growth of phytoplankton and other aquatic vegetation, reduced water clarity, and increased biological oxygen demand. Such water quality and habitat changes may be detrimental to certain SGCN associated with specific lakes. Many SGCN species are heavily dependent on healthy aquatic systems for food sources, such as abundant fish and/or invertebrate populations utilized by eagles, osprey, mink, river otter, muskrat and bats.

Development of shorelands may alter habitat required by terrestrial SGCN that are associated with lacustrine areas, such as bald eagle, osprey and mink. As an example, the
reduction of mature trees by clearing within the riparian area may eliminate eagle and osprey nesting sites and reduce recruitment of woody debris into the littoral zone.

The invasion of lacustrine waters by habitat-altering exotic species and the subsequent control of these exotics may have degraded habitat for some aquatic SGCN. For example, the establishment of Eurasian milfoil in several mesotrophic lakes where blackchin shiners are known to occur has likely displaced native aquatic plant communities on which this fish species is dependent for spawning and refuge. While milfoil control activities, such as herbicide treatment, are conducted to restore lake conditions conducive to water-based recreational pursuits (boating, swimming, sport fishing), the result is loss of vegetative cover now provided by milfoil stands, increased predation on shiners by other resident fishes (e.g., bass, sunfish, pike), as well as the loss of spawning habitat. These pressures on blackchin shiner populations continue until littoral areas are adequately revegetated with native plant species, a process that may take many years.

The deliberate and accidental introduction of plant and animal species to Vermont’s lakes and ponds over the past 200 years has greatly changed natural communities and their ecological functions. Many fish species, including those native to the state as well as ones brought from outside, have been established in waters where they did not naturally occur. For example, largemouth bass, bluegill and northern pike, all native in Vermont to Lake Champlain only, now have transplanted populations in habitats nearly statewide. Rainbow and brown trout originated from the western United States and Europe, respectively, and now are established in many lakes within the state. The distribution of these species was expanded beyond their natural range for the primary purpose of increasing sport fishing opportunities; however, in the past little consideration was given to the negative effects these species have on native ecosystems. More recently, 1997, the exotic alewife was discovered in Lake St. Catherine where previously the species did not exist. This was the first recorded occurrence of alewife in the state. The impacts this species has on native fish communities are well documented, including: (1) out-competing other planktivores for food and causing shifts in zooplankton species composition and size structure; (2) preying on the eggs and larvae of native fishes; and (3) causing significant mortality syndrome in salmon and trout fry (Good 2001). The trans-state movement and introduction of exotic species into natural habitats has become an environmental problem of national scale. Past species introductions changed the current character of many Vermont lacustrine areas, and the problem is a persistent problem for maintaining lakes and ponds in a desired condition well into the future.

Currently dystrophic and high elevation acidic lakes are somewhat less limited by direct development pressures that other lake types are experiencing. On the other hand, these lakes are particularly vulnerable to habitat alteration through the effects of acid deposition.

**Desired Condition (SGCN Needs):** Lacustrine areas directly and indirectly support a host of species, including aquatic invertebrates (insects, crustaceans, mollusks), fishes, reptiles, amphibians, mammals, birds and plants.

Obligate SGCN associated with oligotrophic lakes (e.g., landlocked Atlantic salmon, lake trout, arctic char, round whitefish) require deep, clear, well-oxygenated water for their survival. Potential increases in lake water temperatures due to climate change represent a problem for these oligotrophic lakes and the associated cold-water SGCN.
In contrast, species associated with mesotrophic and eutrophic lakes are more dependent on the high productivity of these lake systems to produce needed food sources and habitat complexity, such as well-established littoral communities for feeding, reproduction and refuge cover.

A number of SGCN, notably the reptiles and amphibians, have home ranges that encompass both lacustrine and terrestrial areas at particular times of the year. For example, spotted and musk turtles, which reside most of the year in lakes and ponds, leave these waters briefly for upland areas to lay eggs. Similarly, lake residing brook trout may seasonally ascend tributary streams to spawn. In contrast, Fowler's toads travel from their usual terrestrial haunts to aquatic habitats to deposit eggs along the shoreline. Forested riparian zones provide nesting and feeding perches for bald eagle and osprey. Mature trees that eventually die and are recruited into the littoral area contribute to forming refuge and basking habitats. Maintenance of water quality conditions characteristic of specific lake types is a requirement of SGCN associated and dependent on those habitats.

The desired condition for all lacustrine communities would include: 1) the existence of intact riparian conditions; 2) the existence of minimally disturbed littoral zones; 3) evolutionary (e.g. trophic) processes occurring at rates not accelerated by disturbance; 4) pollutant levels (e.g. sediment and toxics, including acid deposition) below concentrations that would adversely affect SGCN; 5) absence of exotic species that adversely affect SGCN; 6) unimpeded access by SGCN to habitats required for the maintenance of life cycle functions; and 7) unaltered hydrological and temperature regimes.

**Species of Greatest Conservation Need in Lacustrine Communities (excluding Lake Champlain)**

**High Priority**
- Peregrine Falcon (*Falco peregrinus*)
- Bald Eagle (*Haliaeetus leucocephalus*)
- American eel (*Anguilla rostrata*)
- Bridle Shiner (*Notropis bifrenatus*)
- Blackchin Shiner (*Notropis heterodon*)
- Arctic Char (*Salvelinus alpinus oquassa*)
- Fowler's Toad (*Bufo fowleri*)
- Common Mudpuppy (*Necturus maculosus*)
- Bog/ten/swamp/marshy pond Odonates
- Crustaceans group
- Freshwater Snails Group
- Lakes/ponds Odonates Group
- River/stream Odonates Group
- Silver-haired Bat (*Lasionycteris noctivagans*)
- Eastern Red Bat (*Lasiurus borealis*)
- Hoary Bat (*Lasiurus cinereus*)
- Eastern Pipistrelle (*Pipistrellus subflavus*)

**Medium Priority**
- Osprey (*Pandion haliaetus*)
- Redfin Pickerel (*Esox americanus*)
- Redbreast Sunfish (*Lepomis auritus*)
- Round Whitefish (*Prosopium cylindraceum*)
- Atlantic salmon-landlocked (*Salmo salar*)
- Brook Trout-naturally reproducing populations (*Salvelinus fontinalis*)
- Lake Trout-naturally reproducing populations (*Salvelinus namaycush*)
- Northern Water Snake (*Nerodia sipedon*)
- Common Musk Turtle or Stinkpot (*Sternotherus odoratus*)
- Mink (*Mustela vison*)
- Muskrat (*Ondatra zibethicus*)

**SGCN Note:** Plant SGCN not listed here 25 species. The SGCN invertebrate groups listed here contain numerous species. For more information about a specific Species of Greatest Conservation Need see that species' assessment summary in Appendix A.

Grassland & Hedgerow Summary

Characteristics and Location
Grasslands are landscapes dominated by grasses, sedges and forbs with little to no tree or shrub cover. Most of the larger examples of this community type are the result of current or past agricultural practices. Grassland habitats are also commonly maintained at airports, fairgrounds, landfills and industrial complexes. Smaller grasslands are found in fallow beaver flowages, seasonally flooded areas adjacent to rivers, and sandplain communities, and are covered under separate summaries.

Hedgerows are linear patches of trees or shrubs, often lining field borders or roadsides. Hedgerows enable some species to more fully utilize adjacent grassland communities (for perching, nesting, sheltering or escaping predators), while other species may occupy annual or seasonal home ranges solely within hedgerows. Hedgerows also often serve as travel or dispersal corridors connecting disjunct habitat patches.

Types of Grassland & Hedgerow Communities:
- Hayfields, pastures, old fields, power line and RR right-of-ways, mowed interstate medians, airports, industrial complexes.

- Treed and/or brushy hedgerows lining field edges and roads.

Grassland & Hedgerow Condition

Historical Perspective: Grasslands in Vermont are primarily a result of land clearing for agriculture since European settlement of the area. It has been estimated that early successional forest (1-15 year age class) occupied from 1.1-3.0% of the regional presettlement landscape in areas of northern hardwood forest and 2.4-7.1% of the regional landscape in areas of spruce-northern hardwood forest (Lorimer and White 2003).

Current Condition: Most of Vermont’s grasslands occur in the Champlain Valley and to a lesser extent the Connecticut River Valley and the area around Lake Memphremagog. There are also numerous grasslands of various types and sizes scattered across the rest of the state. Most grasslands are associated with current or past agricultural practices. There are, however, grasslands that are the result of other human activities and are maintained for specific purposes. These include grasslands associated with airports (commercial and private), landfills, fairgrounds, military reservations and industrial complexes (e.g., IBM, Husky, etc.). Most of Vermont’s grasslands are in private ownership, although the state and federal governments own and manage some of these areas. The counties with the highest percentages of land in agriculture and open land are Addison (35.5%), Franklin (29.5%), Grand Isle (25%) and Orleans (22%, primarily in the area surrounding Lake Memphremagog) (U.S. Department of Agriculture. 1997).

Although agriculture practices create and maintain valuable grasslands, recent intensification of these practices has had negative impacts on their quality and availability. Small diversified farming which provided a range of suitable habitat types has given way to larger, more intensively managed farms as a result of improved agricultural techniques. Advances in equipment, fertilizers and extensive use of potent pesticides and herbicides have resulted in greater management of hayfields (early and frequent cutting which disrupts nesting activity), conversion of hayfields to row crops or legumes, and intensive grazing (LaBarr et al. 2004).
Urban and suburban development has also resulted in a loss of grasslands. This loss comes in two forms, the direct loss of grasslands as structures and lawns replace fields, and fragmentation of large grassland areas into smaller parcels rendering them insufficient for use by some breeding grassland bird (e.g., Upland Sandpiper). In Vermont, the urban and suburban growth of Chittenden county is expanding into Franklin and Grand Isle counties to the north and Addison county to the south. As a result there is increasing pressure to develop agricultural lands important to grassland species (LaBarr et al. 2004).

Other factors contributing to loss of quality grasslands include incompatible management of grasslands in non-agricultural settings (i.e., airports). Although airport construction and management has provided suitable habitat for grassland species, mowing regimes, many of which are required by the Federal Aviation Administration (FAA) often disturb nesting activity. Also, a lack of airport expansion planning (new hangers, airplane parking, etc.) which takes into account grassland species has lead to the loss of important grassland habitat at these sites (LaBarr et al. 2004).

More is known about the effects of current conditions on grassland bird species than other SGCN taxa that use grasslands and/or hedgerows. Grassland bird species as a whole have declined steadily throughout their range. Reported results from the U.S. Fish and Wildlife Service Breeding Bird Survey show that declines of grassland birds have been consistently steeper and more widespread than any other assemblage of birds (Askins 1993, Sauer et al. 2001). In Vermont, Upland Sandpiper populations have declined precipitously (Peterson 1999) and Grasshopper Sparrows are considered rare and uncommon (Ellison 1985, Record of Vermont Birds). Both Sedge Wren and Henslow's Sparrow populations have declined to where they may no longer be breeding in the state. Other obligate grassland species, although relatively abundant (i.e., Bobolink and Eastern Meadowlark) have also show significant declines in recent years (LaBarr et al. 2004).

**Desired Condition (SGCN Needs):** A variety of grasslands and hedgerows are needed to conserve the suite of species dependant on these habitat types. For example, Bobolinks utilize large expanses of grassland or fallow hay fields with little or no alfalfa, high litter cover and scattered broad-leaved forbs for nest-site cover (Martin and Gavin 1995). Northern Harrier habitat includes marshy meadows, wet, lightly grazed pastures, old fields, mesic grasslands, and drained marshlands. Densest populations are typically associated with large tracts of undisturbed habitats dominated by thick vegetation (MacWhirter and Bildstein 1996). Upland Sandpipers prefer large grassland areas (20-40 ha) with a mosaic of grassland types as areas of short grass are used for feeding while areas of taller grass (10-30 cm) are used for nesting. All three of these aforementioned species benefit from grasslands that are not subjected to early (before July 15) mowing. American Kestrels nest in cavities or nest boxes in most open areas (< 30% canopy cover; Smallwood and Bird 2002). Gray Fox, New England Cottontail, Eastern Rat Snake, Smooth Green Snake and Brown Snake all utilize hedgerows for foraging, denning or nesting, and/or as movement corridors.
Species of Greatest Conservation Need in Grasslands & Hedgerows

High Priority
- Grasshopper Sparrow (Ammodramus savannarum)
- Upland Sandpiper (Bartramia longicauda)
- Northern Harrier (Circus cyaneus)
- Sedge Wren (Cistothorus platensis)
- Peregrine Falcon (Falco peregrinus)
- Fowler’s Toad (Bufo fowleri)
- Wood Turtle (Clemmys insculpta)
- Eastern Racer (Coluber constrictor)
- Timber Rattlesnake (Crotalus horridus)
- Eastern Rat Snake (Elaphe obsoleta)
- Grassland Butterflies Group
- Moths Group
- Eastern Red Bat (Lasiurus borealis)
- Hoary Bat (Lasiurus cinereus)
- Woodland Vole (Microtus pinetorum)
- Pygmy Shrew (Sorex hoyi)
- New England Cottontail (Sylvilagus transitionalis)
- Southern Bog Lemming (Synaptomys cooperi)

Medium Priority
- Cooper's Hawk (Accipiter cooperii)
- Henslow's Sparrow (Ammodramus henslowii)
- Blue-winged Teal (Anas discors)
- Short-eared Owl (Asio flammeus)
- Chimney Swift (Chaetura pelagica)
- Black-billed Cuckoo (Coccyzus erythropthalmus)
- Bobolink (Dolichonyx oryzivorus)
- American Kestrel (Falco sparverius)
- Purple Martin (Progne subis)
- Eastern Meadowlark (Sturnella magna)
- Lesser Yellowlegs (Tringa flavipes)
- Barn Owl (Tyto alba)
- Blue-winged Warbler (Vermivora pinus)
- Smooth Green Snake (Liochlorophis vernalis)
- Brown Snake (Storeria dekayi)
- Eastern Ribbon Snake (Thamnophis sauritus)
- Long-tailed Weasel (Mustela frenata)
- Hairy-tailed Mole (Parascalops breweri)
- Common Gray Fox (Urocyon cinereoargenteus)

SGCN Notes: Plant SGCN not listed here: 23. The SGCN invertebrate groups listed here contain numerous species. For more information about a specific Species of Greatest Conservation Need see that species' assessment summary in Appendix A.

Mines and Quarries Summary

Characteristics and location
Mines may provide many or all of the habitat qualities of natural caves and can even provide better habitat in some instances. Similarly, quarries may mimic natural cliffs, outcrops, and talus slopes. These human-created cultural habitats, due to the history of Vermont are found statewide and may augment the natural habitats available to wildlife.

Types of Mines and Quarries:
- Mines in Vermont include gold, silver, iron asbestos, and talc mines.
- Quarries in Vermont include marble, granite, and slate quarries
- In some cases gravel pits and road cuts may provide habitat

Mines & Quarries Condition
Current Condition: Mines and quarries occur throughout the state. Some are long abandoned, some more recent, and others currently used to lesser or greater extents. The sites vary in their structural stability and some are very dangerous (large sections of the Elizabeth Mine have collapsed) Bats are known to use some mine sites as hibernacula. Peregrine falcons may nest or roost on the walls of some rock cuts. Mine vents and other vertical rock structure may provide nesting habitat for swifts. Small-footed bats might seek shelter in between and under large rock talus created by mining or quarrying operations. In some instances the sites are toxic due to leaching of mine tailings. Some sites have the entrances blocked, become dumping areas, or recreational vehicle parks.

Desired Condition (SGCN Needs): Some mines and quarry site provide conditions that certain species select. A mine that has appropriate temperatures and humidity may provide good wintering habitat for bats. Like caves, if the conditions change or if disturbances occur, the site may no longer be suitable habitat and can even cause the death of bats using the mine. Some rattlesnake reports historically have been from slate quarries in proximity to existing or historical den sites. Quarries could provide foraging and basking habitat as well as escape cover. Rock piles with abundant spaces that extend below the frost line could even provide denning sites. Sites providing necessary habitat for SGCN are important and should be conserved.

Subterranean Summary

Characteristics and Location

Subterranean areas are defined as below-surface natural features (mines are addressed under Cultural Habitats) that consist of both aquatic and terrestrial conditions. Because these areas are below ground, there is limited human access to locate and inventory these sites. Consequently, there is little information on their abundance, distribution, and condition.

Some of the best information on subterranean areas comes from the caving community. Members of the Vermont Cavers Association have particular interest in locating, exploring, and even surveying these areas. Some of the earlier documentation of Vermont caves is from John Scott (1959) and, more recently, Peter Quick (1994).

Most of Vermont’s caves are relatively small, ranging from less than 100 feet underground to several hundred feet. Some caves contain passages that may continue far beyond what has been accessed. Most Vermont caves are solutional, meaning they have been formed through erosion from moving water.

While caves are found throughout Vermont, most of the known caves are located in southern Vermont, particularly the Taconics and Southern Green Mountains regions. These areas also are known to have the geologic features most associated with underwater springs and streams that would provide subterranean aquatic habitats.

Subterranean Condition

Current Condition: Due to the geologic nature of the habitat type, caves remain in much of their original structure. Many of the more accessible caves do exhibit signs of graffiti and evidence of the destruction or removal of cave formations such as stalagmites and stalactites. Historic accounts of some caves document the loss of beautiful formations by visitors. Currently, 3 caves are gated and locked to control human visitation.

Subterranean areas provide a very consistent environment of temperature, relative humidity, and air flow. While these variables are likely important to the overall condition, there is very limited information on these variables. Changes in structure and hydrology could greatly affect these habitat provided by subterranean areas.

There are 6 species of bats known to hibernate in Vermont caves. Bats are one of the better studied wildlife species associated with subterranean areas, and have been surveyed in caves going back into the 1930s (Trombulak et al. 2001). Trend data from hibernacula surveys does provide for some evaluation of the value of specific caves to particular bat species and populations. Recent surveys indicate that caves may hold as few as less than 10 bats to as many as over 23,000. Interest and understanding in the invertebrate community associated with caves is just beginning.

Little is known about the condition of the subterranean aquatic habitats.

The primary activities resulting in the loss or degradation of subterranean areas involve either human disturbance to either the cave structure (thereby affecting temperature, humidity, or air flow) or the species using the area and pollutants to the aquatic elements of the subterranean areas.
**Desired Condition:** Subterranean areas provide habitat for a small number of SGCN in the state. However, subterranean areas provide a critical habitat component for the survival of these species. Subterranean areas should remain intact, with limited human alteration or influence from above-ground pollutants. Many of the SGCN associated with subterranean areas use the sites for denning or hibernation, but also spend a disproportionate amount of the year in the surrounding area (e.g., fall swarming for bats or breeding and birthing for rattlesnakes).

A total of 8 SGCN are associated with subterranean area.

Buildings & Other Structures Summary

Characteristics and location
Buildings and structures may provide habitat for wildlife, generally in the form of shelter, when they provide appropriate conditions (i.e., temperature and humidity) and are relatively secure from disturbance. Sometimes the structures provide habitat for prey species (mice) that attract the foraging SGCN (snakes). In other cases the structures may simply become an extension of the natural landscape, such as basking and foraging sites for skinks. Structures used by wildlife are located throughout Vermont, but are not always known or appreciated as habitat for wildlife.

Types of Buildings and Other Structures Providing Habitat for SGCN:
- Barns and other outbuildings
- Abandoned or little used buildings
- House attics
- Bridges
- Dam sites
- Power poles and other vertical structures (possibly)
- Towers or tall buildings that mimic cliffs

Condition of Buildings & Other Structures
Current Condition: Buildings and other structures may be used by wildlife under a variety of circumstances. Bats may roost in abandoned building attics, the attics of occupied dwellings, or in outbuildings or covered bridges. Peregrine falcons may nest on ledges of tall buildings, tower, or bridges although we don’t have any currently nesting in such locations at present. Small-footed bats might seek shelter in between and under large rock talus used to armor dams. Osprey may nest on power poles near water and chimney swifts may build their nests inside chimneys.

Desired Condition (SGCN Needs): Some buildings and other structures provide conditions that certain species select. If the site is relatively undisturbed and secure over time, large number of some species may come to depend on the site (e.g., large bat maternity colony). Change the light regime or air circulation, and the conditions may no longer be as suitable. In some cases the surrounding area, or even the specific geographic location, may determine if a structure is used by a SGCN. Only barns located near existing skink populations will be used by that species and a power pole used by osprey for nesting has to be within flying distance of fishable waters.

Appendix C
Definitions for the Problem & Strategy Categories found in the Wildlife Action Plan

Definitions of the Problem Categories ................................................ 1
Definitions of Strategy Categories ...................................................... 7
Habitat-Related Problem Categories

**Climate Change:** Long-term changes linked to global warming and other climate issues that can lead to major changes in habitat availability (e.g., high elevation habitats), vegetative composition and location (e.g., the movement up in elevation or north in latitude, invasion by exotic pests) as well as climate variability (e.g., change in snow depth, rainfall and/or natural disturbances).

**Habitat Alteration/Degradation:** A lessening of the quality of a habitat by human action stopping short of complete conversion (examples include: the reduction of mast production from a forest stand, the riprapping a streambank, and significant land use changes adjacent to a habitat such as replacing a forest stands on the edge of a wetland with a housing development. In the last case, the development would be a conversion of the forest stand and, if not designed properly, could also degrade the wetland). Habitat Conversion, Habitat Fragmentation, Hydrologic Alteration, Sedimentation, Pollution and Inadequate Distribution Of Successional Stages are closely related categories.

**Habitat Conversion:** The complete transformation or loss of a habitat by human action (examples include: filling a wetland to create a grassy field, converting a forest into a parking lot, or damming a stream to create a reservoir). Habitat Alteration/Degradation, Habitat Fragmentation, Hydrologic Alteration, and Inadequate Distribution of Successional Stages are closely related categories.

**Habitat Fragmentation:** The breaking up of habitats into smaller, non-contiguous patches as a result of habitat conversion (e.g., housing, commercial development, roads, utility lines). Fragmentation can: 1) render important habitats inaccessible (such as isolating a den site from a feeding site), 2) breakdown of the metapopulation structure of a species (for example grassland butterflies, spotted salamander, and tiger beetles); and, 3) degrade remaining habitat patches through edge effects that favor edge-tolerant species such as raccoons and crows, as well as invasive exotic species that can out-compete native and rare species. The result of habitat fragmentation is often increased predation, increased mortality, reduced mobility and changes in habitat microclimates. Habitat Alteration/Degradation, Hydrologic Alteration and The Impacts off Roads and Trails are closely related categories.

**Hydrologic Alteration:** Changes in the flow, periodicity or quality of a surface or subsurface water system (examples include a dam on a river preventing historic fluctuations in water level and mining activities causing a perennial seep to run dry). Dams can also increase water temperature. If warm water was identified as a problem then that problem would be placed in the pollution category. Hydrologic Alteration is a subset of Habitat Alteration but is a significant enough problem to warrant a separate category.

"But Vermont is 78% forested. How could habitat conversion, alteration or fragmentation be a problem?"

First, many Species of Greatest Conservation Need require non-forested habitat. This plan is concerned about loss and fragmentation to non-forested habitat too.

And, second, Though Vermont's forests look intact from the sky, if you peer below the canopy it's clear that 78% forested does not mean 78% unfragmented.

See figure 1 for details.
Why be concerned about wildlife if Vermont is 78% forested? As these maps indicate, though forest cover is significant (map 1-A) in many cases forests are fragmented into smaller parcels with few large blocks far from development (maps 1-B, 1-C). While some wildlife species thrive in smaller parcels, large contiguous blocks provide more suitable habitat (and reduce potential conflict with humans) for Lynx, American marten, Mountain lion, Black bear, River otter, Northern goshawk, Red shouldered hawk and others. As the number and size of blocks decrease, it becomes more difficult for these species to persist.

1-A. Forest blocks bordering developed lands
1-B. Forest blocks at least 100m from edge of developed lands
1-C. Forest blocks at least 400m from edge of developed lands

Fig 1: Vermont Contiguous Forest Blocks

Contiguous Forest Block refers to an area of forested land either without roads or with low densities of class IV roads, and little or no human development (buildings, parking areas, lawns, gravel pits). Contiguous forest may have various age classes of forest cover and include other habitat types such as wetlands or grasslands that are part of the overall contiguous habitat complex.

Maps depict forested habitat in blocks of at least 500 acres. Blocks include actively and passively managed forest. Source data are 1992-1993.
**Impacts of Roads and Trails:** Transportation corridors that bring people, disturbance, and exotics to a habitat or directly impact a Species of Greatest Conservation Need (examples include: road kill, bird species whose mating calls are drowned out by the noise of road traffic, a road corridor that speeds the spread of an exotic invasive species, poorly planned ORV or hiking trails that cause wildlife to abandon a den site). Habitat Fragmentation, habitat Alteration/Degradation and Impact of Roads & Trails are closely related categories.

**Inadequate Distribution of Successional Stages:** The lack of either late, mid or early successional habitat in appropriate size and/or juxtaposition (examples include ruffed grouse and woodcock which prefers early successional forest stands, American marten which prefers late-successional stands and lynx which depends on a mix of stages).

**Inadequate Disturbance Regime:** A disturbance regime is re-occurring process that disrupts a habitat, ecosystem, populations, and/or substrate causing significant change to a system (Picket and White). Many species have adapted to these disturbances and depend upon them to maintain habitats (examples include: the loss of beaver created wetlands, and a dam preventing the yearly flooding of floodplain forests that brings nutrients to the site and creates opening for early successional vegetation).

**Invasion by Exotic Species:** The introduction and spread of nuisance exotic and native species (plants and animals). These species may lead to the elimination of populations, threats to long-term stability or extirpation by out-competing a native species, displacing its food source or altering a key process or function of a habitat. Note that this category includes both exotic species and invasive native species such as cowbirds and sea lamprey. Exotic disease and parasites are addressed separately in the disease category.

**Parcelization:** The separation of a large parcel of land into multiple smaller parcels. Parcelization is a significant driver of habitat fragmentation (and is often driven itself by tax policy). Parcelization can make it difficult to deliver management programs or present access issues which could impede actions benefiting SGCN even when fragmentation is not a problem (e.g., when a single 800-acre parcel is broken into many smaller lots some of the new landowners may choose to post their land while others may close logging roads).

**Sedimentation:** Excessive inputs (in frequency and/or abundance) of solid material (inorganic or organic solid fragments) that are carried and deposited by wind, water, or ice to a water body. These materials have a negative impact on Species of Greatest Conservation Need through their physical presence (example: soils washing into a stream from a construction site and smothering fish eggs and other aquatic species that live in the spaces between rocks and gravel in a streambed). Sedimentation was broken out from the habitat alteration/degradation category because of its significant impact on aquatic species. Note: a problem that exerted a negative chemical impact on wildlife (e.g., road salt), would be listed in the Pollution category.

**Non-Habitat-Related Problem Categories**

**Competition** Where two or more species are in competition of the same limited resource (e.g., space, food, nutrients) there will be a decrease of survival, growth rate
and/or reproduction of competing individuals (for example: fisher, bobcat and coyote have overlapping habitat needs and preference for prey).

**Disease:** Any disease causing agent such as, fungi, bacteria and viruses (examples include: rabies, West Nile disease, whirling disease, chronic wasting disease, hemlock wooly adelgid, and sudden oak death). Diseases are often transmitted by parasites, a related problem.

**Genetics:** A reduction of survival or fecundity of a species due to inbreeding depression (the mating of close relatives) usually due to small and isolated populations, and outbreeding depression (the mating of different locally adapted populations). Examples include lake sturgeon and timber rattlesnake for whom inbreeding depression and genetic drift may be distinct possibilities due to small and isolated populations. Outbreeding depression can be a problem for native baitfish whose locally adapted genes may be swamped out by the accidental release of relatives taken from other waters in the state or elsewhere.

**Harvest or Collection:** The legal or illegal taking of biological resources (such as hunting, trapping, collecting, fishing) for commercial, recreation, subsistence, research, or management purposes (examples include: the accidental taking of spruce grouse or American marten by a hunter or trapper, illegal collection of wood turtles for sale in the pet trade, and the harvesting of eels).

**Incompatible Recreation:** Recreational activities (outside of established transport corridors) that directly impacts SGCN or their habitats (examples include: bird watchers that get too close to nesting common loons can cause the loons to abandon their nest, and off-road vehicles operated outside of approved areas can run through vernal pools degrading the pool and crushing spawning amphibians and their eggs). Because of the scale of impact, the construction of a golf course or ski area would be listed in Habitat Conversion or Habitat Alteration categories respectively. Incompatible Recreation is also closely related to Impacts of Roads & Trails.

**Loss of Food Base or Prey Base:** The disappearance of a food source important to a species' survival (examples include: lynx which feeds primarily on snowshoe hare and the whippoorwill whose primary diet of flying insects has been decreased).

**Loss of Relationship with Other Species:** A species whose existence depends upon another for a process, function or product (examples include the larvae of many mussel species will attach to fish and depend on these fish for dispersal). Many insects, including butterflies and moths, have specific relationships with host plants that serve as its sole food. In some cases the host plant also conveys a chemical protection to the insect.) This category differs from the Loss of Prey Base category in that there are no alternatives (e.g., lynx and whippoorwill can take other prey, monarch butterflies won't persist without milkweed to feed on and to provide chemical protection from predators).

**Parasitism:** A relationship between two species in which one benefits (the parasite) and the other (the host) is harmed, (Smith 1980) although not directly killed (examples include: ticks, sea lamprey parasitizing lake whitefish and lake trout). Parasites may
transmit diseases to the host therefore disease is a closely related problem. Examples include ticks transmitting Lyme disease and mosquitoes transmitting West Nile virus.

**Pollution:** The introduction of exotic materials (other than sediments) from point and non-point sources. This includes: chemicals and toxins such as industrial chemicals in the air, land, and water; excess nutrients from farm and municipal sewage plants; garbage and other solid waste; radioactive materials; road salt; excessive noise; excessive heat; and light pollution that disturbs animals and disrupts migration patterns. Note: Sediments were broken out from this category because of its significant impact on some water bodies. Greenhouse gasses such as carbon dioxide and methane would be covered in the Climate Change category.

**Predation or Herbivory:** Species or habitats negatively impacted by wildlife species that eat them (examples include: raccoons and skunks that eat wood turtle and spiny softshell turtle eggs and moose over-browsing vegetation and preventing the regeneration of a forest stand. This category differs from Competition in that competition is two or more species vying for the same specific resource, whereas predation is one species eating another.

**Reproductive Traits** Species whose specific reproductive strategies make it vulnerable, such as species producing very few offspring because they take a long time to reach sexual maturity and/or take a long time between reproductive events (examples include: lake sturgeon and wood turtle).

**Trampling & Direct Impacts:** Non-recreational, and sometimes inadvertent, negative impacts to a species (examples include the crushing of wildlife by agricultural equipment operating in a farm field, vehicles operating off-road, the killing of rattlesnakes or bats out of antipathy for the species, increased nest abandonment by brown thrashers due to the proximity of people). Impacts to a habitat would be assigned to the Habitat Degradation/Alteration and perhaps Habitat Conversion. Incompatible Recreation and Impacts of Roads & Trails are closely related categories.

**Bibliography**

Appendix C: Definitions for Strategy Categories Used in the Wildlife Action Plan

Element number four of the eight congressionally required elements of a Wildlife Action Plan requires that states describe “conservation actions proposed to conserve the identified species and habitats and priorities for implementing such actions.”

We identified strategies to address the problems impacting each of Species of Greatest Conservation Need (SGCN) and habitats in the Action Plan. Strategies identified in the Action Plan are based on the best science available today as well as our strategic assessment of needs and priorities of all wildlife species. In the coming years, as monitoring data on SGCN and conservation actions becomes available, as priorities change, or new problems or opportunities arise, strategies may need to be revisited. Not every strategy in this report will be eligible for State Wildlife Grant funding. Furthermore, it may not be suitable, or feasible, for the VT Fish & Wildlife Department to implement some of the strategies in this report, however, some conservation partners may find them fitting and practical.

Strategies are described in the Action Plan in short narratives in each species summary and in each habitat summary. Strategies are intentionally broad, directional, and nonspecific so as not to constrain our selection of actions for implementing them. For example, a strategy such as “provide technical assistance to landowners to maintain or improve riparian habitat for Species of Greatest Conservation Need” allows for different approaches to providing that assistance and leaves the door open to a variety of providers to implement. Where strategy implementation is to be funded by the State Wildlife Grant program the approach should be consistent with the Department’s mission and strategic plan, and precise procedures will be detailed in operational plans once the Action Plan is finalized.

Vermont’s Wildlife Action Plan was designed to be a strategy for the state, not just the Fish & Wildlife Department. While the department may be responsible for implementing many of the strategies in this report, it will be Conservation partners, however, that may be the more logical and appropriate leaders for others, due to their skills and expertise, staffing, history, location, available resources and constituencies.

Each of the strategies identified in the Action Plan were assigned to one of 27 categories in six major classes. The categories were adapted from the Proposed Taxonomy of Conservation Actions (Salafsky 2005). The taxonomy was developed as a means to standardize terminology (not practices) among conservation practitioners worldwide. Many states have used these same categories to organize the strategies and actions in their Action Plan.

It should be noted that the categories are used solely for the purpose of organizing and grouping strategies developed by Action Plan teams and committees. It was not our goal to create strategies for every category. A few categories were not applicable to the species or habitats in Vermont whereas others were deemed not as effective. The categories with the greatest number of associated strategies were sections 4a, research; and 4c technical assistance.
Land/Water Protection

a) Creating Publicly-Owned Protected Areas: Setting up or expanding public parks, forests and other protected areas where wildlife conservation is a primary management objective (examples include: wildlife management areas, state forests, municipal lands)

b) Creating Privately-Owned Protected Areas: Setting up or expanding private reserves and other protected areas where wildlife conservation is a primary management objective (examples include: private lands managed by non-profit conservation or hunting groups)

c) Easements: Setting up protection of some specific aspect of a resource on public or private lands (examples include: development rights, wild & scenic river designation)

2) Land/Water/Species Management

a) Protected Area Management: Generally managing protected areas where wildlife conservation is a primary management objective (examples include: site design, training park staff, managing water levels).

b) Compatible Resource Use: Promoting use of resource lands (where wildlife management is not a primary objective) to be compatible with conservation (examples include: promoting sustainable logging, grazing, fishing, hunting, farming, aquaculture, energy development, transportation infrastructure).

c) Invasive Species Control & Prevention: Dealing with invasive and/or alien plants, animals, and pathogens (examples include: developing boat wash stations, pulling noxious weeds from a habitat).

d) Habitat Restoration: Enhancing degraded or restoring missing habitats (examples include: clayplain forest restoration and riparian tree plantings). If a strategy specifically targets one or two species we consider it a species restoration strategy. If it specifically targets three or more species we consider it a habitat restoration strategy.

e) Natural Processes Restoration: Enhancing or restoring natural ecosystem functions (examples include: prescribed burns, dam removal and restoration of historic flow regimes, fish ladders).

f) Species Restoration: Enhancing or restoring specific plant and animal populations (examples include: translocating spruce grouse from Canada to Vermont, and erecting artificial nesting boxes/platforms for bluebirds and osprey.) If a strategy specifically targets one or two species we consider it a species restoration strategy. If it specifically targets three or more species we consider it a habitat restoration strategy.

g) Ex-Situ Conservation: Protecting wildlife out of its native habitats (examples include: captive breeding of bald eagles and creating regional refugia for New England cottontail rabbit).

3) Law & Policy

a) Legislation: Making, changing, influencing, or providing input into formal legislation at all levels: international, national, state/provincial, local (examples include: lobbying to make the State Wildlife Grant program permanent, addressing greenhouse gas emissions).
b) **Policy & Regulations:** Making, changing, influencing, or providing input into policies and regulations affecting the implementation of laws at all levels: international, national, state/provincial, local (examples include: providing data to policy makers, development of wildlife harvest regulations).

c) **Planning & Zoning:** Developing, changing, influencing, or providing input into plans governing natural resource use and allocation (examples include: municipal zoning, public or private management plans for ecoregions, sites, habitats, or species, commenting on zoning plans, developing a town ordinance).

d) **Standards:** Setting, changing, influencing, or providing input into voluntary standards that govern practices (examples include: best management practices for forestry, habitat guidelines for state lands).

e) **Compliance & Enforcement:** Monitoring and enforcing compliance with laws, policies & regulations, plans, and standards (examples include: water quality standard monitoring, enforcement of ATV regulations).

4) **Research, Education & Awareness**

   a) **Research:** Conducting and disseminating research to improve knowledge about conservation issues (examples include: conducting inventories for SGCN, developing habitat maps, demonstration projects for sustainable forestry)

   b) **Technical Assistance, Training, Workshops:** Enhancing knowledge, skills and information exchange for practitioners, landowners, stakeholders, and other relevant individuals in structured settings outside of degree programs (examples include: providing technical assistance to landowners, monitoring workshops, conferences, learning networks)

   c) **Lifelong Learning:** Enhancing knowledge and skills of practitioners, stakeholders, and other relevant individuals through non-structured means (examples include: writing a how-to manual for landowners or towns and communities, stakeholder education on proper ORV use)

   d) **Awareness Raising and Communications:** Raising conservation awareness and providing information through various media (examples include: websites, newsletters, puppet shows, etc.)

5) **Economic & Other Incentives**

   a) **Linked Enterprises:** Developing enterprises that directly depend on natural resources as a means of influencing behaviors, attitudes, and beliefs (examples include: ecotourism, sustainable forest product harvesting).

   b) **Substitution:** Promoting products and services that substitute for environmentally damaging ones (examples include: floodplain restoration in place of dams and bank reinforcement and promoting recycling and use of recycled materials)

   c) **Financial Incentives & Market Forces:** Using market mechanisms to influence behaviors, attitudes, and beliefs (examples include: forestry certification, positive incentives, negative incentives, forest banking, valuation of ecosystem services such as flood control)
d) **Conservation Payments**: Using direct or indirect payments to influence or reinforce behaviors, attitudes, and beliefs (examples include: landowner payment programs).

c) **Non-Monetary Values**: Using non-market forces to change behaviors, attitudes, and beliefs (examples include: landowner/land manager recognition awards).

6) **Capacity Building**

a) **Institutional Development**: Creating or providing non-financial support & capacity building for non-profits, government agencies, and for-profits (examples include: creating new local land trusts)

b) **Alliance Development**: Forming and facilitating partnerships, alliances, and networks of organizations (examples include: Action Plan Conservation Partners, Vermont Monitoring Cooperative, Vermont Sportsmen’s Federation).

c) **Conservation Finance**: Raising and providing funds for conservation work (examples include: State Wildlife Grants small grants program, private foundations, debt-for-nature swaps).

Conservation Partners Charter for the Comprehensive Wildlife Conservation Strategy

Public Participation Goal: The Department of Fish and Wildlife (FWD) wishes to create a Comprehensive Wildlife Conservation Strategy (CWCS) for the state of Vermont—one that meets the needs of all fish and wildlife as well as participating partners and the FWD. Therefore, FWD will collaborate with the CWCS Conservation Partners in each aspect of their charge.

Promise to the Public: The Vermont Fish and Wildlife Department will look to the Conservation Partners committee for direct advice and innovation in formulating solutions. We will strive to create a CWCS that Partners can be a part of and we will look to Conservation Partners to help implement the CWCS upon its completion.

Committee Charge
The Comprehensive Wildlife Conservation Strategy Conservation Partners committee is established to provide advice to FWD in the development and implementation of the Comprehensive Wildlife Conservation Strategy for the state of Vermont. The committee will:

- Review federal guidelines and sideboards for developing a CWCS.
- Review CWCS drafts and final report
- Nominate experts for staffing of technical teams.
- Review the interim draft CWCS report and provide constructive and timely feedback to the Steering Committee.
- Review final draft CWCS report and provide constructive and timely feedback to the Steering Committee.
- Help implement the Comprehensive Wildlife Conservation Strategy upon completion.

Responsibilities
In order to achieve their mission the CWCS Conservation Partners will:

- Meet as needed to develop an understanding CWCS development issues (approximately 3-4 meetings/year).
- Complete assigned tasks and projects by dates specified on the CWCS timeline
- Work together to represent their organizations’ views and respect other organizations’ views and opinions.
- Provide staff and experts from their organizations to participate as appropriate on the technical teams.
- Serve as a liaison to their respective organizations to keep members informed of CWCS progress.

Committee Members
Members may include representatives of local, state and federal agencies, NGOs, landowners, utilities, wildlife related businesses and others.
Committee Charge
The CWCS Steering Committee meets regularly with the CWCS Coordinator for briefing, guidance, and review of planning efforts. The committee provides leadership and organizational commitment to ensure success of the CWCS, as well as expertise in conservation biology and wildlife management. It champions the CWCS process and ensures that sufficient resources are allocated to the effort. Tasks may include but are not limited to:

- Review of federal guidelines and sideboards for developing a CWCS.
- Review of charters for CWCS teams and committees, as developed by the CWCS Coordinator.
- Introducing the planning effort and team charges to the other committees and teams at initial meetings and to Fish and Wildlife Department staff.
- Suggesting criteria that might be used for identifying species of greatest conservation need.
- Recommending tools and data sets that technical teams will use and providing guidance in the consistent use of the data.
- Suggesting criteria to assist in prioritizing conservation actions.
- Reviewing public involvement materials and drafts of the CWCS as necessary.

Responsibilities
The CWCS Steering Committee:

- Has statutory responsibility for completion of the CWCS and management of State Wildlife Grant funds.
- Encourages meaningful participation and buy-in among partners and the Fish and Wildlife Department staff during CWCS development.
- Appoints members to Species Teams and Integration Team.

Committee Members
Ron Regan FWD Operation Director, Tom Decker FWD Wildlife Director, Eric Palmer FWD Fisheries Director, Scott Darling FWD District Biologist, Steve Parren FWD Nongame and Natural Heritage Program Coordinator, Tom Wiggins FWD Fish Culture Program Chief/Department Planner, Jon Kart CWCS Coordinator.

Public Participation Goal: The Department of Fish and Wildlife (FWD) wishes to create a Comprehensive Wildlife Conservation Strategy (CWCS) for the state of Vermont—one that meets the needs of all fish and wildlife as well as participating partners and the FWD. Therefore, FWD will collaborate with the Conservation Strategy Review Team in each aspect of their charge.

Promise to the Public: The Vermont Fish and Wildlife Department will look to the CWCS Conservation Strategy Review Team for direct advice and innovation in formulating solutions.

Committee Charge
The CWCS Conservation Strategy Review Team is established to provide advice to FWD and Conservation Partners in the development of a comprehensive wildlife conservation strategy for the state of Vermont. The team will:

- Review federal guidelines and sideboards for developing a CWCS.
- Review existing wildlife and conservation plans.

Responsibilities
In order to achieve their mission the CWCS Conservation Strategy Review Team will:
- Complete assigned tasks and projects by dates specified on CWCS timeline
- Review limiting factors and draft strategies developed by the Integration Team.
- Develop additional strategies as needed and prioritize strategies.
- Work together, to bring the team’s knowledge and expertise of species, habitats/natural communities and conservation strategies to the development of a statewide Comprehensive Wildlife Conservation Strategy.

Committee Members
Conservation Partners as well as designees from the environmental education and wildlife law enforcement communities.
Integration Team Charter for the Comprehensive Wildlife Conservation Strategy

Public Participation Goal: The Department of Fish and Wildlife (FWD) wishes to create a Comprehensive Wildlife Conservation Strategy (CWCS) for the state of Vermont—one that meets the needs of all fish and wildlife as well as participating partners and the FWD. Therefore, FWD will collaborate with the Integration Team in each aspect of their charge.

Promise to the Public: The Vermont Fish and Wildlife Department will look to the CWCS Integration Team for direct advice and innovation in formulating solutions.

Committee Charge
The CWCS Integration Team is established to provide advice to FWD and Conservation Partners in the development of a comprehensive wildlife conservation strategy for the state of Vermont. The team will:

- Review federal guidelines and sideboards for developing a CWCS.
- Review existing wildlife and conservation plans.
- Analyze criteria for the identification of “species of greatest conservation need” used by CWCS development teams in others states and in conservation biology literature.
- Advise Species Teams where needed to ensure consistent analysis and application of recommended procedures across taxonomic groups.

Responsibilities
In order to achieve their mission the CWCS Integration Team will:

- Complete assigned tasks and projects by dates specified on CWCS timeline.
- Develop criteria for identifying species of greatest conservation need.
- Monitor the progress of Species Teams to ensure deadlines are met.
- Coordinate work and facilitate communication between Species Teams.
- Analyze reports of the Species Teams and identify gaps in existing information.
- Address special habitat and natural community needs.
- Synthesizes reports of the Species Teams and strategies developed by the Conservation Strategy Review.
- Consult with the Conservation Strategy Review Teams.
- Work together, to bring the team’s knowledge and expertise of species, habitats/natural communities and conservation strategies to the development of a statewide Comprehensive Wildlife Conservation Strategy.

Committee Members
Facilitators of the Species Teams and additional Fish and Wildlife Department staff, Conservation Partner staff and other experts as assigned by the Steering Committee.
Species Team Charter for the Comprehensive Wildlife Conservation Strategy

revised 4/28/2004

Public Participation Goal: The Department of Fish and Wildlife (FWD) wishes to create a Comprehensive Wildlife Conservation Strategy (CWCS) for the state of Vermont—one that meets the needs of all fish and wildlife as well as participating partners and the FWD. Therefore, FWD will collaborate with the Species Teams in each aspect of their charge.

Promise to the Public: The Vermont Fish and Wildlife Department will look to the Species Teams for advice and innovation in formulating solutions.

Team Charge
The Species Teams of the Comprehensive Wildlife Conservation Strategy are established to provide expertise on various wildlife species. The teams will:

- Review federal guidelines and sideboards for developing a CWCS.
- Review existing wildlife and conservation plans pertinent to the team’s work.
- Apply the criteria provided by the Integration Team to create a list “species of greatest conservation need.”
- Identify locations and conditions of habitats and natural communities of listed species of greatest conservation need.
- Identify limiting factors to the listed species of greatest conservation need and their habitats.
- Recommend draft strategies for managing species of greatest conservation need.
- Develop plans to monitor identified species and effectiveness of conservation strategies.
- Address comments submitted by the Conservation Partners and FWD staff during the interim review and incorporate where appropriate into the Species Team’s report to the Integration Team.

Responsibilities
In order to achieve their mission the CWCS Species Team will:

- Meet on a schedule as needed by the team.
- Complete assigned tasks and projects by dates specified on CWCS timeline.
- Work together, to bring their knowledge and expertise of species and habitats/natural communities for the development of a statewide CWCS.
- Identify gaps in existing information.

Team Members
Members should have demonstrable training and experience in a taxonomic specialty sufficient to allow them to critically analyze life history requirements, limiting factors to population persistence, and needed conservation actions. Teams include 1) Birds, 2) Fish, 3) Invertebrates, 4) Mammals, 5) Plants, 6) Reptiles & Amphibians.

Subject: Comprehensive Wildlife Conservation Strategy

Dear Conservation Partner,

I’m writing to encourage you and/or your organization to get involved in the development of Vermont’s Comprehensive Wildlife Conservation Strategy (CWCS). The CWCS is a new statewide (and national) effort, funded by the federal State Wildlife Grants program, to identify species of greatest conservation need and their habitats and to define actions that will conserve them. Two key elements set the CWCS apart from other planning efforts: 1) it will be an all species strategy; and 2) it will be a strategy for Vermont, not just for the Fish and Wildlife Department. On March 24, 2004 we’ll hold the first meeting of CWCS Conservation Partners. We’d like you or someone from your organization to attend.

The State Wildlife Grants program (SWG) was created by Congress in 2001 to support fish and wildlife conservation for under-funded species. The Vermont Fish and Wildlife Department has since become eligible for more than $2.5 million in federal conservation dollars—with millions more available in the future. SWG requires that we develop a statewide Comprehensive Wildlife Conservation Strategy by Oct 1, 2005.

The Comprehensive Wildlife Conservation Strategy is not just another plan. Congress has charged State Fish and Wildlife Departments with developing statewide all-species conservation strategies. The actions defined by Vermont’s CWCS will be eligible for hundreds of thousands of dollars of federal funds annually for implementation. Furthermore, Conservation Strategies are being produced by every state, the territories and the District of Columbia. Together, the strategies will provide a collective “plan” for safeguarding our wildlife legacy—efficiently and cost-effectively.

**How will the CWCS be developed?** The CWCS will grow out of a joint effort of many conservation partners. Congress charged State Fish and Wildlife Departments with leading the CWCS development but Congress also made it clear that it expects the help, advice and expertise of other state and federal agencies, conservation organizations and the general public.

**Why you’re needed.** A strategy is only as good as its components. We need your expertise, your ideas, your priorities and your solutions. To be effective, the strategy must be shaped by the people who know Vermont, and who understand the issues, the challenges and the threats to wildlife.

**What’s in it for you?** The Conservation Strategy will help create a vision for the future direction of wildlife conservation and will likely influence future funding. By participating,
you will expand and strengthen networks and coalitions for conserving our wildlife resources. By working collectively for our common conservation interests we will insure a health future for wildlife in Vermont.

**What will Vermont’s Comprehensive Wildlife Conservation Strategy look like?**
Congress has left much of the development of the CWCS up to us, though there are a number of required elements including the identification of species of greatest conservation need and their habitats, the identification of threats and the development of actions to conserve these species. The Conservation Strategy should also consider the full array of Vermont’s wildlife and habitats—taking advantage of good work already done in Vermont and filling in missing gaps.

In order to develop a plan by 2005, we’ve created an approach that employs several interactive teams, including:

- *Conservation Partners*: an advisory committee that will assist the development of the Conservation Strategy.
- *Species Advisory Team*: a technical team that will develop criteria for selecting species of greatest conservation need and synthesize and develop overarching conservation solutions.
- *Species Teams*: a technical team that will identify species in need, their habitats, threats and conservation actions.

I am contacting you because of your commitment to Vermont’s wildlife. Please consider becoming a Conservation Partner in the creation of our state’s Comprehensive Wildlife Conservation Strategy, a commitment that will run through October 2005.

I encourage you to get involved in this important project for the future of Vermont’s wildlife. **If you or another member of your organization is interested in participating as a Conservation Partner please contact Jon Kart at 802-241-3652 or jon.kart@anr.state.vt.us by March 10, 2004.** If you or your organization is unable to participate as a Conservation Partner, we will try to provide other meaningful ways for your involvement in the planning process and welcome a chance to talk with you about potential roles.

Please feel free to contact me, or Jon Kart, with any questions, comments, or ideas for the development of a statewide Comprehensive Wildlife Conservation Strategy. I look forward to working with you.

Sincerely,

Wayne A. Laroche
Commissioner

- Meeting registration form
Conservation Partners Meeting for the Comprehensive Wildlife Conservation Strategy
March 24th, 2004 • Lake Morey Resort • Fairlee, VT

Meeting Agenda
9:30   Registration and coffee
10:00  Welcome, Commissioner Wayne Laroche
10:15  Review of the Day, Fisheries Director Eric Palmer
10:20  History of Wildlife Funding in Vermont, Wildlife Director Tom Decker
10:40  Wildlife Conservation Opportunities, Operations Director Ron Regan
11:00  The Comprehensive Wildlife Conservation Strategy process,
      CWCS Coordinator Jon Kart
11:30  Questions & Answers
Noon  Lunch (provided)
1:00   Reconvene
1:05   Breakout sessions to refine the Comprehensive Wildlife
      Conservation Strategy process
2:30   Where do we go from here?
3:00   Adjourn

Directions to Lake Morey Resort, Fairlee, VT
Lake Morey Resort 800-423-1211

From the North: Take I-91 south to Exit 15. Turn right off Exit 15. Then take the first
immediate right followed by the first left. Lake Morey Resort will be on your right (it
is less than a minute from the exit).

From the South: Take I-91 north to Exit 15. Turn left off Exit 15. Then take the first
immediate right followed by the first left. Lake Morey Resort will be on your right (it
is less than a minute from the exit).

From the West:
Interstate Directions: Take I-89 South to White River Junction to I-91 North to Exit
15. Turn left off Exit 15. Then take the first immediate right followed by the first
left. Lake Morey Resort will be on your right (it is less than a minute from the exit).

Back road Directions: (faster if you are coming from Montpelier or points West of
Montpelier.) Take I-89 to Exit 7. Take Rt. 62 East to Rt. 302 East to Rt. 25 East to
Bradford, VT. In Bradford take I-91 South one exit to Exit 15. Turn right off Exit
15. Then take the first immediate right followed by the first left. Lake Morey
Resort will be on your right (it is less than a minute from the exit).
Conservation Partners Meeting Registration
Comprehensive Wildlife Conservation Strategy
March 24th, 2004 • Lake Morey Resort • Fairlee, VT

Please join us at the initial meeting of Conservation Partners in the development of Vermont’s Comprehensive Wildlife Conservation Strategy. We need to move forward developing the Conservation Strategy, so please let us know of your interest by returning this form by March 10, 2004.

Register with Jon Kart, CWCS Coordinator by March 10th, 2003

Registration procedures
1) Fill out the form below and…
2) Submit your registration by telephone, email, fax or US mail.
   - Call: Jon Kart 802-241-3652
   - Email: jon.kart@anr.state.vt.us
   - Fax: 802-241-3295
   - US Mail: Jon Kart CWCS Coordinator, Vermont Fish and Wildlife Department,
     103 South Main Street, 10 South, Waterbury, VT 05676

Comprehensive Wildlife Conservation Strategy Update

Dear CWCS Conservation Partner,

As promised at our meeting at Lake Morey on March 24th, I’m writing with an update on progress made on Vermont’s Comprehensive Wildlife Conservation Strategy. The past few weeks have been busy as the Steering Committee, Species Team leaders and I have worked with the feedback we received from you to improve the CWCS process. I believe that we’ve done a good job of it and, we will soon be ready to set loose the Species Teams to do their jobs. However, before that happens I wanted to send you this CWCS update that includes:

1) A responsiveness summary addressing the comments, questions and feedback we’ve received so far from Conservation Partners and others interested in conserving Vermont’s wildlife. In general we have sought to balance the desire for greater input, more frequent updates and opportunities for information sharing with your requests not to be deluged with email and regular mail.

2) Changes and improvements made to the CWCS process. Based on your suggestions we’ve made a couple of changes to the process originally outlined at the Lake Morey meeting on 3/24/04. In particular we’ve added a new Conservation Strategies Review team to the array of CWCS committees and teams. This is in direct response to requests by Conservation Partners for added participation in the development of conservation strategies. We’ve also change the name of the Conservation Science Team to Integration Team to better reflect the role that this team will play.

3) Appointments to the CWCS technical teams and updated list of Conservation Partners

4) Technical Team Meetings and Meeting Policies for technical team meetings.

5) Next steps in the development of Vermont’s Comprehensive Wildlife Conservation Strategy.

Please review the documents on the following pages and let me know if you have any further comments or suggestions.
1. Responsiveness Summary to feedback and comments received during and after the CWCS meeting at Lake Morey Resort, Fairlee, VT on March 24, 2004.

Dear Conservation Partner,

Many, many excellent, thought-provoking comments and suggestions were received at the Comprehensive Wildlife Conservation Strategy meeting at Lake Morey on March 24th. We have done our best to incorporate your recommended improvements/amendments to the CWCS process. Below you’ll find an edited and condensed list of the comments (similar comments were grouped to reduce redundancy) along with Fish and Wildlife Department (FWD) actions and responses. Comments are listed in bold text below. If a number in parentheses follows a comment it signifies the number of times a similar response was received. Responses follow each comment in plain text.

Project Scope

Taking a species by species approach to conservation won’t work. There are too many species and not enough is known about most of them. An approach focusing on habitats/natural communities and threats to them will be more effective. (9)

The Fish and Wildlife Department chose to develop the Comprehensive Wildlife Conservation Strategy using a species by species format so that the product will be more understandable to the lay audience. However, we realize that 1) in many cases the needs of multiple species overlap; and, 2) that we have species of wildlife in Vermont that are poorly documented or understood. In both of these cases, management for habitats/natural communities is the prudent and most cost-effective way to address the needs of many species. The Integration Team will likely employ habitat/natural community conservation measures when it begins synthesizing the work of the six species teams. Furthermore the Conservation Strategy Review Team (a new team, see the Process & Teams section below) will likely take a similar approach.

In assessing threats look at common threats across species (also strategies).

Each of the six species teams (birds, fish, invertebrates, mammals, plants, and reptiles and amphibians) will likely do this for wildlife within their charge. The Integration Team and Conservation Strategy Review Team will do the same for all species across all taxa as they look for overarching solutions to conservation threats.

Will new species be addressed? Will species be reintroduced?

Species that have not historically been found in Vermont will likely not be addressed as part of Vermont’s CWCS (except where they pose threats to native species). Regarding reintroductions: federal guidelines for CWCS development and implementation define wildlife as “any species of wild, free-ranging fauna including fish, and also fauna in captive breeding programs the object of which is to reintroduce individuals of a depleted indigenous species in a previously occupied range.” Therefore species reintroduction is permissible.

We don’t know if Vermont’s Comprehensive Wildlife Conservation Strategy will ultimately include a recommendation or recommendations for species reintroductions, but discussions about the efficacy of reintroduction of extirpated wildlife should certainly take place amongst the technical teams.
Define the end goal (products) for the CWCS early in order to establish direction for the process. (5)

Congress’ requirement that state Comprehensive Wildlife Conservation Strategies must address the broad range of wildlife and wildlife-related issues (keep common species common) and place appropriate priority on “species of greatest conservation need” (focus on wildlife that have not benefited from wildlife and sportfish restoration funding) is a tall order. Our goal is to develop a CWCS that will: 1) identify species, habitats, threats and strategies; and, 2) serve as a blueprint that all interested agencies and organizations can use to proactively conserve Vermont’s wildlife.

What is the Fish and Wildlife Department’s commitment (time and money)? (3)

The Vermont Fish and Wildlife Department is fully committed to the development and implementation of the Comprehensive Wildlife Conservation Strategy. We’ve hired one full-time staff person as project coordinator (Jon Kart), seven FWD staffers are leading technical teams with six other staffers serving as technical team members. Additional FWD staff will assist in CWCS development and implementation on project-by-project bases (examples include public outreach and data development). Finally, senior level staff serves as the CWCS Steering Committee ensuring department-wide support.

Coordinate with other states so we can learn what they are doing, and so that we can work together on larger regional issues rather than just looking within our own borders. Also: Rely on the Vermont Biodiversity Project and other resources. (2)

Interstate coordination is the seventh of eight Congressional requirements for all Conservation Strategies: Coordinate the development, implementation, review, and revision of the CWCS with Federal, State, and local agencies and Indian tribes. One of the many great things about this CWCS process is that all 50 states along with a number of territories and Native American tribes are developing their Conservation Strategies at the same time. Interstate meetings and communication are being facilitated by the US Fish and Wildlife Service and the International Association of Fish and Wildlife Agencies.

The work Vermont Biodiversity Project and other planning efforts will certainly be reviewed in the development of Vermont’s CWCS. We do not want to reinvent wheels. If good science and planning information exists, we hope to use it wisely.

What happens after October 2005?

The implementation phase begins. We hope that most, if not all of our Conservation Partners will join the Fish and Wildlife Department in implementing strategies outlined in the Comprehensive Wildlife Conservation Strategy.

Process & Teams

The organization chart needs to be shortened condensed— too much too soon. (3)

The mix of teams and committees proposed to tackle the CWCS mirrors the complexity of the task at hand. Collecting and analyzing scientific data and developing strategies and policies are difficult in themselves. Maximizing the participation of a broad array of partners—without overtaxing them—makes CWCS development doubly challenging. We believe that the process outlined in this document is as streamlined as we can get and still involve as many voices as possible.
The CWCS process needs to integrate policy early on instead of just focusing on biology and ignoring broader policy issues. Species teams should not be only taxonomists and biologists. Bring in others for strategy development. (4) Species “threats and strategies” should be separate team “boxes” that conservation partners are involved with (i.e., a “strategies” team).

The initial three steps in development of a Comprehensive Wildlife Conservation Strategy are primarily biological: 1) Identify wildlife distribution and abundance; 2) Identify the location and assess the condition of key habitats and community types; and, 3) Identify key threats and research needs. Inserting policy issues at this stage would be premature. Once these steps have been accomplished then we can begin identifying conservation strategies and other policy issues.

We have added an additional team to the equation (see the top of the right column of the attached organizational chart). The Conservation Strategy Review Team (CSR) to the process. The CSR will receive a draft list of threats, goals and strategies facing wildlife from the Integration Team. They will review the draft and provide feedback to the Integration Team about the efficacy of the strategies. The CSR can develop additional strategies where they see fit.

What are the criteria for placing people on a species team?
Species team members should have training and experience in a taxonomic specialty sufficient to allow them to critically analyze life history requirements, threats to population persistence, and needed conservation actions. The Steering Committee sifted through the list of technical team nominees looking for people with technical expertise for as a broad a suite of species as possible. We tried to not select people with a single species focus in order to get the broadest coverage of wildlife expertise on a team while keeping the team size small (to maximize effectiveness). We expect that technical team members will participate to share their expertise, not to represent their organization’s or agency’s position.

Work partners and volunteers more in the process and plan.
We’ve done our best to include a broad array of partners on the various technical teams while keeping in mind advice from several Conservation Partners that as teams get larger their effectiveness wanes. We’ve tried to keep the size of our Species Teams to five-seven people. We do welcome additional organizations and agencies to participate as Conservation Partners. If you know of additional entities that should be involved in the CWCS, please have them contact Jon Kart, CWCS Coordinator at 802-241-3652 or jon.kart@anr.state.vt.us.

Somewhere in the process there must be a place to resolve conflicts on products. (2) The Integration Team will address conflicts that develop within and among the Species Teams and the Conservation Strategies Review Team. If conflicts cannot be settled by the Integration Team then they will be addressed by the CWCS Steering Committee and, if needed, the Commissioner of the Fish and Wildlife Department.

Open the Steering Committee to others than Fish and Wildlife employees. (3) The steering committee should solicit partners’ guidance on pending issues before a final decision is made.
State Fish and Wildlife departments have been given statutory responsibility by Congress for completion of Comprehensive Wildlife Conservation Strategies and for management of State Wildlife Grant funds. For efficiency and accountability we believe that the Steering Committee should remain Fish and Wildlife Department directors only. The
role of the Steering Committee is to provide coordination and continuity during the development of the CWCS. For those that want additional input and oversight during the development of the CWCS we’ve created the Conservation Strategy Review Team (see above).

Communications with Conservation Partners and the Public

Use a web-based process to allow immediate updates and input. (4) The interested public should have a conduit for submitting comments.

We are currently working on improvements to the Fish and Wildlife Department’s website to allow for the posting of timely updates and meeting schedules and to announce important dates and decision-making points. This site should include interactive opportunities to allow Conservation Partners and the general public to ask questions and post comments directly to the site. Partners and the general public could then respond directly to the list of species of greatest conservation need, alert us to what they deem to be key threats to wildlife, etc. We will also explore opportunities to use interactive television to make our meetings more accessible to partners and the general public.

Alert the public more frequently, not just for the final review. (3) Could conservation partners be used for public outreach?

A media plan is in development. We want to encourage print, radio and TV outlets to spotlight CWCS efforts and projects currently funded by the State Wildlife Grants. We hope that Conservation Partners will inform their members and the general public about the CWCS too. A sample story for organization’s newsletters will be drafted and distributed to all Conservation Partners. To get additional information or to provide feedback the public will be directed to the website mentioned above.

Supply partners with the list of reference materials used by the species teams.

Technical teams will cite all references used in the development of their reports. Where possible, lists of reference materials expected to be used during future team meetings will be posted for Conservation Partner review. Please note that the timeline for completing this project is a short one and it may not be possible to provide much if any advance notice of specific topics of future meeting and/or lists of reference materials to be used. Partners could also supply teams with relevant reference materials.

Time needs to be built in process so that the advisory group can be brought up to a common level (maybe use web-based application to get information out). (2) Prefer regular check-in/update opportunities for Conservation Partners that won’t limit the ability of teams to get work done.

Unfortunately, time is in short supply, both for completing the CWCS by the Congressionally mandated deadline of October 1, 2005 and for many of you busy with your own projects and organizational responsibilities—as many Conservation Partners have told us. We will do our best to provide Conservation Partners with the information they need to stay informed and knowledgeable. We will explore web-based opportunities for disseminating and sharing information. We will also explore opportunities for using interactive television. This latter idea may prove more useful to the technical teams.
We can arrange to have regular, brief, targeted updates posted to the VT Fish & Wildlife Department’s website. An email update of CWCS progress can also be sent out regularly.

Outreach
Where are representatives from Forest, Parks and Recreation and other departments?
The Lake Morey meeting was aimed at executive directors of agencies and organizations to introduce the CWCS to the state. Forest, Parks and Recreation was fully represented by Operations Director Ed Leary. Since that meeting we’ve met with additional FPR directors and with directors of other agencies to identify key individuals within the department who should be taking the lead for their agencies.

All landowners need to be involved and at an earlier level (include Farm Bureau) (2)
Outreach to private landowner may be a role for some of the Conservation Partner organizations.
The Vermont Grange and several consulting foresters/landowner representatives were at the Lake Morey meeting. The Farm Bureau is a CWCS Conservation Partner but unfortunately could not attend the meeting in Lake Morey.

If one or more Conservation Partners would like to play a role in outreach to private landowners, please contact Jon Kart CWCS Coordinator at 802-241-3652, jon.kart@anr.state.vt.us

Academics need more involvement, particularly at species level.
Several have been added to technical teams.

Committed youth (e.g. selected high school students) should be involved at partner level.
If one or more Conservation Partners would like to take the lead in identifying and educating interested youth, please contact Jon Kart CWCS Coordinator at 802-241-3652, jon.kart@anr.state.vt.us

Roles of the Comprehensive Wildlife Conservation Strategy Teams and Committees

**Conservation Partners** (state & federal agencies, non-profit organizations, large landowners, utilities, State legislators, academics, and others)
- Provides guidance and recommendations to the Steering Committee.
- Reviews interim and final CWCS drafts.
- Nominates experts for participation on technical teams.
- Helps implement the CWCS upon its completion.

**Steering Committee** (Fish and Wildlife Department Directors, Nongame and Natural Heritage Program Coordinator, FWD Planner)
- Executive body for the CWCS development and implementation with statutory responsibility for completion of the CWCS and management of State Wildlife Grant funds.
- Provides leadership and organizational commitment to ensure success of the CWCS.
- Encourages meaningful participation and buy-in among partners.
- Appoints members to technical teams.

**CWCS Coordinator** (Fish and Wildlife Department staff)
- Manages the project.
- Supports activities of the technical teams.
- Manages outreach and communications.

**Conservation Strategy Review (CSR)** (Conservation Partners as well as designees from the environmental education and wildlife law enforcement communities)
- Reviews threats and draft strategies suggested by the Species Teams.
- Develops additional strategies as needed.

**Integration Team** (Species Team facilitators plus additional Fish & Wildlife staff and non-staff experts).
- Develops criteria for designating species of greatest conservation need.
- Keeps Species Teams on schedule.
- Synthesizes reports of the Species Teams and strategies developed by the Conservation Strategy Review
- Identifies gaps in information and addresses special habitat and natural community needs.
- Prioritizes strategies and solutions to conservation challenges.

**Species Teams** (Fish and Wildlife staff, partners, and other experts as needed) Species teams: 1) Birds, 2) Fish, 3) Mammals, 4) Reptiles & Amphibians, 5) Invertebrates, 6) Plants
- Develop and refine lists of species of greatest conservation need.
- Develop monitoring and performance measures.
- Recommend draft strategies for managing species of greatest conservation need.
- Address comments made by Conservation Partners during interim review.

**Interested Conservation Public**
- Will be kept informed of the status of the CWCS by the CWCS Coordinator.
  Methods of communication may include brochures, newsletters, website, public meetings, media outlets.
- Will be asked to provide comments on the final draft.
3) Appointments to the CWCS Technical Teams as of 5/4/04

4) CWCS Technical Team Meetings and Meeting Policies

The Integration team and the six species teams will begin meeting in May (the Conservation Strategy Review team will start in September). These meeting will be open to the public. Once the teams develop their meeting schedules I will contact you again via email to inform you of the schedules. When our CWCS website is running we will post the schedules there.

The eight technical teams (Conservation Strategy Review Team, Integration Team and the six Species Teams) are charged with developing much of the science and strategies for Vermont’s Comprehensive Wildlife Conservation Strategy. Time is short and these are huge responsibilities. To help these teams work effectively the following meeting polices have been developed. Team members and meeting guests are urged to respect them.

- Team members are expected to share their expertise in wildlife conservation, not to represent their organization’s or agency’s position.

- Team appointments are for individuals, not organizations—no proxies for meeting representation will be allowed. To ensure continuity and team efficiency from meeting to meeting the same organization representative must come to each meeting.

- Team meetings are working meetings with full agendas and members need to focus on their time-sensitive responsibilities. Non-team members are welcome to attend primarily as observers. Non-members may provide timely and appropriate information. However, little time can be devoted to review or to help non-members get “up-to-speed.” A few minutes will be reserved at the beginning and end of each meeting to take comments and answer questions.

- To encourage free and open discussions and information sharing during meetings, team members and guests need to recognize that all documents and information produced and developed by a team, and discussions had within and among teams, are to be considered drafts, or for discussion purposes only, until officially approved by a team. If information is shared outside the team, all recipients should be made aware of the preliminary nature of the information.

If warranted, additional policies and meeting guidelines may be adopted.
5) Next Steps

The Integration team and the six species teams will begin meeting in May (the Conservation Strategy Review team will start in September). Once the teams develop their meeting schedules I will contact Conservation Partners again via email with the meeting schedules and will post schedules to a VT-CWCS as soon as possible. You are welcome to attend meetings. Please note, however, that these will be working meetings with full agendas. Guidelines for meeting formats and protocols can be found in the previous section of this letter.

The first step for the Integration Team will be to define criteria for the designation of “species of greatest conservation need.” Once this occurs, the six species teams will begin developing their lists of species of greatest conservation need. If you are interested in the criteria for designating of “species of greatest conservation need” let me know and I will email it to you. When the lists of species of greatest conservation need are developed by the species teams I will collect them and send them to you for review.

Once the species teams have generated their lists of species of greatest conservation need they will further assess the abundance and distribution of these species, and identify habitats for the species of greatest conservation need. It is possible that this may result in adjustments to the species lists.

While this is taking place I will be working on the CWCS outreach plan to inform the general public about Vermont’s Comprehensive Wildlife Conservation Strategy.

The Conservation Strategy Review team will meet in September for two or three meetings to review a draft list of goals, threats and strategies developed by the species teams and to develop additional strategies as needed.

Though much work lies ahead of us, I’d like to thank you for your help so far. Your feedback and suggestions have improved the process we will use to complete this project. Your help on technical teams and as Conservation Partners providing guidance and oversight during the coming months will ensure that we do our utmost to conserve Vermont’s wildlife. Please feel free to contact me with any additional comments or suggestions. We remain open to making the process more effective and responsive.

Thanks for your time.

Sincerely,

Jon Kart

Comprehensive Wildlife Conservation Strategy Update#2

Hello,

It's been a busy and productive summer for the teams developing Vermont's Comprehensive Wildlife Conservation Strategy and I want to take a moment to provide you with a progress report. I'd also like to inform you that after a lot of work, a VT-CWCS website is finally up and running. This website will make it easier for you to access background information on the CWCS, track the progress of the project and team meeting schedules.

The address is [http://www.vtfishandwildlife.com/swg_home.cfm](http://www.vtfishandwildlife.com/swg_home.cfm)

I encourage you to alert members of your respective organizations and other friends of wildlife and interested parties to the existence of this site.

Progress Report by team/committee:
The Conservation Partners has not met since it first got together at the Lake Morey Inn in March 2004. A summary and recommendations that came from that meeting was part of the Conservation Partners Update #1 which was sent to you in May. If you did not receive that update please let me know and I will send it to you.

The Conservation Partners will not meet again until a draft of the CWCS is ready for your review. We originally projected that date to be this November, but a thorough reality check informs us that a draft won't be ready till late February. We value your time and we want to give you something substantive to work with. An updated schedule follows at the end of this note.

Most of the work on the CWCS during the last three months has been done by the six Species Teams (Bird, Fish, Invertebrate, Mammal, Plant, and Reptile & Amphibian). They have the huge task of conducting the basic species assessments—pouring over distribution data and discussing meta-population and viability reports. Their short term goal is to develop a list of Species of Greatest Conservation Need. A *draft* list should be complete by mid-September. When it is ready I will post it to the website and send you a reminder.
Once that list is complete, the Species Teams will focus on identifying key habitats for the Species of Greatest Conservation Need, conducting threat and opportunity assessments and developing conservation strategies.

That work should be completed by Nov 1st. Then the Integration Team takes over and will join together the work of the six Species Teams. Over the last couple of months the Integration Team has met to provide guidance to the Species Teams and to develop a database and integration plan that will be used to collect and analyze data developed by the Species Teams.

A draft Comprehensive Wildlife Conservation Strategy will be prepared for the Conservation Strategy Review team (CSR) to review at their initial meeting in early December and subsequent meeting in early January. The CSR will review the document and strategies and make recommendations to add/change strategies, gather public input on the strategies, and works with the Integration Team to finalize the strategies.

The CWCS development schedule follows below.

**CWCS Timeline**

**2004**
- **Sept**  Species Teams complete drafts of Species of Greatest Conservation Need (SGCN) lists.
- **Sept**  Fish & Wildlife Dept. Commissioner and Integration Team review draft SGCN list
- **Sept**  Draft SGCN list is then distributed to Conservation Partners and Conservation Strategy Review team
- **Nov**  Species Teams complete their draft reports (reports go to the Integration Team)
- **Dec**  Integration Team completes their review of the Species Teams reports and completes a draft of the CWCS (this is sent to the Conservation Strategy Review team (CSR)).
- **Dec**  Conservation Strategy Review team meets to review the draft CWCS and begins work on strategies assessment/development

**2005**
- **Jan**  Conservation Strategy Review team reconvenes to complete its report
- **Jan**  Integration Team reviews the CSR report, drafts a responsiveness summary and incorporates CSR recommendations into the CWCS
- **Jan**  Draft CWCS to Fish & Wildlife Dept. Commissioner and Steering Committee
Feb  Draft & comments back from the Commissioner and Steering Committee
Feb  Draft of CWCS is sent to Conservation Partners for review
Mar  Conservation Partners meet to discuss and review the draft CWCS
Apr  Steering Committee completes and distributes a responsiveness summary based on Conservation Partner feedback.
May  Public review of the draft CWCS begins
May  Public review ends
July  CWCS completed
January 9, 2005

Comprehensive Wildlife Conservation Strategy Update#3

Dear Conservation Partner,

Happy New Year. I'm writing with an update about Vermont's Comprehensive Wildlife Conservation Strategy (CWCS) as well as to share some good news about the State Wildlife Grants program with you.

The teams developing the CWCS have made great progress since the last update. The CWCS Species Teams (Birds, Fish, Invertebrates, Mammals, Plants and Reptiles & Amphibians) have just about completed full assessments of our Species of Greatest Conservation Need (SGCN). This includes identifying known distribution and abundance, habitat descriptions, threats and limiting factors, research and inventory needs and conservation strategies for each SGCN.

Our CWCS Integration Team is quickly piecing together the myriad species, habitat and landscape components into a recognizable plan. They have had to integrate information on more than 250 wildlife species and 400 plants into the 25 habitat types that will form the backbone of our report. In addition the Conservation Strategy Review team held its first organizational meeting and will soon begin prioritizing threats and reviewing strategies.

Our pace has been fast and furious. As we hurtle towards our July 2005 deadline I doubt the pace will slow. We've had to make a little more room in our timeline for both the Integration Team and Conservation Strategy Review team to complete their tasks. This will ensure that the draft CWCS that we bring to you will be complete. We now anticipate a Conservation Partner Review meeting in early May to review the draft document and a public review in June. I will contact you with specific dates as soon as possible.

For those of you who just can't wait to see what a comprehensive strategy looks like, I recommend that you check out North Carolina's version. NC is a few months ahead of Vermont (and most other states) and has posted several sections of their CWCS on the web for the public review. You can find it at http://www.ncwildlife.org/pg07_WildlifeSpeciesCon/pg7c1_3.htm. Vermont's CWCS will be organized similarly.
CWCS in the News: Our CWCS has received a good deal of media attention recently. This includes a Free-Press editorial (1/2/05), a Times-Argus article (12/30/04) (links below). The Associated Press evidently picked up the story too. Please let me know if you saw/heard a story elsewhere as I'm trying to keep track of them.

Burlington Free Press: Editorial 1/2/05:
http://www.burlingtonfreepress.com/bfpnews/editorial/sunday/1000h.htm

Times-Argus: Article 1/30/04:

CWCS Outreach to members and constituents: If your organization or agency has a newsletter or website, please consider including a notice about this project and upcoming public review opportunities in your next issue. A sample article follows at the end of this message, please feel free to adapt it as needed. I would also be happy to give a presentation about the CWCS at one of your meetings.

From the Department of Good News: Though most programs in the recently passed federal budget received significant budget cuts, the State Wildlife Grants program (SWG) actually grew to $69 million from $67.5 million the previous year. SWG provides funding to States to prevent wildlife species from becoming endangered. Vermont will receive more than $600,000 in SWG funds to continue our work conserving Vermont's wildlife and to start implementing the CWCS. This is certainly good news. It also underscores the strong bipartisan support that wildlife conservation and the State Wildlife Grants have in Congress and with the current Administration.

If you have questions about this update or anything else related to the Comprehensive Wildlife Conservation Strategy please contact me anytime at 802-241-3652 or jon.kart@anr.state.vt.us. You can also find information at the VT CWCS website:
http://www.vtfishandwildlife.com/swg_home.cfm. I encourage you to alert members of your respective organizations and other friends of wildlife and interested parties to the existence of this site.

Thank you for your help.

Sincerely, Jon

Jon Kart
CWCS Coordinator
Vermont’s Wildlife Get a Check-Up

An unprecedented evaluation of Vermont wildlife is underway. [your organization] the Vermont Fish & Wildlife Department and biologists, ecologists, sportsmen and conservationists representing more than 60 agencies and organizations have teamed-up to give Vermont's wildlife a check-up.

From to black bear to golden-winged warbler, silver redhorse to blue-spotted salamander, experts are gauging the health of wildlife populations and developing prescriptions for healthy wildlife futures.

Next fall, when the work is complete, Vermont will have its first Comprehensive Wildlife Conservation Strategy (CWCS). "The CWCS will be a strategic vision for conserving the state’s wildlife, one that all conservation-minded agencies and organizations can get behind," according to Jon Kart, CWCS Coordinator for the VT Fish & Wildlife Dept.

Development of the CWCS is driven by the federal State Wildlife Grants program (SWG). Preventing wildlife from becoming endangered is SWG's goal. Vermont has received more than $2.5 million from SWG since the program's inception in 2001. "In these tight budgets times, the State Wildlife Grants program allows us to reach out and better conserve and manage more wildlife than ever before" said Wayne Laroche, Commissioner of the Fish & Wildlife Dept.

Vermont is home to 42 species of reptiles and amphibians, 58 mammals, 94 fish, 235 birds, more than 2,000 plants and many, many more insects, mollusks and other invertebrates. Assessing the status of each of these species is a huge task requiring an effort of unmatched cooperation.

Step one in developing the CWCS was identifying Vermont's Species of Greatest Conservation Need. These species were selected based on criteria such as species rarity, vulnerability to habitat fragmentation or loss, and threat by exotic plants or animals. Then teams assessed habitat quality and identified significant threats to the species. Now conservation strategies are being developed for species and their habitats.

A review draft of the CWCS and public comment period will available during the spring of 2005. Wildlife enthusiasts, landowners, businesses and the general public are encouraged to track and take part in CWCS development. More information can be found on the Vermont CWCS website: www.vtfishandwildlife/swg_home.cfm.
February 24, 2005

Comprehensive Wildlife Conservation Strategy Update#4

Dear Conservation Partner,

I'm writing with a short CWCS Conservation Partner Update and an offer to talk to your board or membership about the Comprehensive Wildlife Conservation Strategy.

The Comprehensive Wildlife Conservation Strategy is taking shape quickly as our Species Teams and Integration Team piece together reports on our Species of Greatest Conservation Need and their habitats. In addition, our Conservation Strategy Review team met for the third time last week. We received great comments and ideas on how to improve the CWCS and we're doing our best to incorporate those suggestions now.

We expect to have a draft ready for you to review in late April. Based on your feedback we will then prepare a public review draft. We will then hold public meetings on the CWCS in June.

In preparation for these events I'd like to offer to give a presentation on the CWCS to your organization's board or general membership. Please let me know at your earliest convenience if you are interested and specific date(s) that your group meets. Also, if you are looking for material for your newsletter or website, please consider adapting the sample article that follows below.

Thanks for your interest.

Sincerely, Jon
---The following is a sample article about the CWCS. Please free to adapt it to best fit your agency’s or organization’s newsletter or website---

**Vermont’s Wildlife Get a Check-Up**

An unprecedented evaluation of Vermont wildlife is underway. [your organization] the Vermont Fish & Wildlife Department and biologists, ecologists, sportsmen and conservationists representing more than 60 agencies and organizations have teamed-up to give Vermont's wildlife a check-up.

From to black bear to golden-winged warbler, silver redhorse to blue-spotted salamander, experts are gauging the health of wildlife populations and developing prescriptions for healthy wildlife futures.

Next fall, when the work is complete, Vermont will have its first Comprehensive Wildlife Conservation Strategy (CWCS). "The CWCS will be a strategic vision for conserving the state’s wildlife, one that all conservation-minded agencies and organizations can get behind," according to Jon Kart, CWCS Coordinator for the VT Fish & Wildlife Dept.

Development of the CWCS is driven by the federal State Wildlife Grants program (SWG). Preventing wildlife from becoming endangered is SWG's goal. Vermont has received more than $2.5 million from SWG since the program's inception in 2001. "In these tight budgets times, the State Wildlife Grants program allows us to reach out and better conserve and manage more wildlife than ever before" said Wayne Laroche, Commissioner of the Fish & Wildlife Dept.

Vermont is home to 42 species of reptiles and amphibians, 58 mammals, 94 fish, 235 birds, more than 2,000 plants and many, many more insects, mollusks and other invertebrates. Assessing the status of each of these species is a huge task requiring an effort of unmatched cooperation.

Step one in developing the CWCS was identifying Vermont's Species of Greatest Conservation Need. These species were selected based on criteria such as species rarity, vulnerability to habitat fragmentation or loss, and threat by exotic plants or animals. Then teams assessed habitat quality and identified significant threats to the species. Now conservation strategies are being developed for species and their habitats.

A review draft of the CWCS and public comment period will available during the spring of 2005. Wildlife enthusiasts, landowners, businesses and the general public are encouraged to track and take part in CWCS development. More information can be found on the Vermont CWCS website: [www.vtfishandwildlife/swg_home.cfm](http://www.vtfishandwildlife/swg_home.cfm).
April 29, 2005

Comprehensive Wildlife Conservation Strategy Update #5

Dear CWCS Conservation Partner,

I'm writing with a short CWCS Conservation Partner Update.

When I last wrote to you (Feb 2005, Update #4) about the development of Vermont's Comprehensive Wildlife Conservation Strategy (CWCS) I stated that we hoped to have a draft of the CWCS ready for you to review in late April. We'll, it is now April 29 and the draft is not yet ready. The reason for the delay is that, recognizing the scope and importance of the CWCS, our agency secretary has requested additional time for our three Agency of Natural Resources commissioners to complete their review of a rough draft of the document.

The commissioners will complete their review by June 1st. We will then address comments from our commissioners and will prepare draft for you to review in mid-June. Based on your feedback we will then prepare a public review draft and have it ready for distribution by mid to late-July. The federal deadline for submission to the US Fish & Wildlife Service is October 1.

In preparation for these events I'd like to offer to give a presentation on the CWCS to your organization's board and/or general membership. A number of groups have taken us up on this offer already. These briefings have been great opportunities for information exchange and idea sharing. Please let me know at your earliest convenience if you are interested and specific date(s) that your group meets.

Thanks for your interest. Feel free to contact me if you have any questions, concerns or comments.

Sincerely, Jon Kart

Go to www.vtfishandwildlife/swg_home.cfm for more information about Vermont's CWCS.
May 16, 2005

CWCS Update #6—Partner Meeting and Report Release

Dear CWCS Conservation Partner,

I'm writing to inform you of a meeting to be held Friday June 24 to present and discuss the draft Comprehensive Wildlife Conservation Strategy (CWCS) report. The meeting will run from 9am-noon and will be held in the Old Dorm Lounge at Vermont Technical College in Randolph, VT (directions below).

The draft CWCS report will be available to you at least one week prior to the meeting when we post it to the CWCS website (www.vtfishandwildlife.com/SWG_home.cfm). I will alert you when it is ready. Comments on the draft will be welcome at least through July 18.

I will send more details about the meeting as they develop. The agenda is as follows:
  9-9:30 Registration, coffee
  9:30-9:40 Welcome - Commissioner Laroche
  9:40-9:55 the Future of Wildlife Conservation
  9:55-10:25 Vermont's CWCS report (process and recommendations)
  10:25-10:35 Break
  10:35-noon Questions & Comments

In addition, I again offer to give a presentation on the CWCS to your organization's board and/or general membership. These briefings have been great opportunities for information exchange and idea sharing. Please let me know at your earliest convenience if you are interested and specific date(s) that your group meets.

Thank you for your interest. Feel free to contact me if you have any questions, concerns or comments.

Sincerely, Jon Kart

Directions to the Vermont Technical College:
- Take I-89 to exit 4.
- From the Exit 4 ramp, turn onto Rt. 66 heading uphill away from McDonalds. Proceed 3/4 mile to intersection at top of hill. -Drive straight through the intersection to access campus from main entrance.
- Look for signs to the Old Dorm Lounge

Go to www.vtfishandwildlife/swg_home.cfm for more information about Vermont's CWCS.
CWCS Update #7—Partner Meeting and Report Release

Dear CWCS Conservation Partner,

On behalf of the many Conservation Partners and Vermont Fish & Wildlife Dept staff that have been working on Vermont's Comprehensive Wildlife Conservation Strategy (CWCS), I am pleased to announce that the Conservation Partner draft of the CWCS is now available at our CWCS website http://www.vtfishandwildlife.com/swg_cwcs_report.cfm. There you can view and download report chapters (recommended) or the entire report as a single file (NOT recommended, it's a BIG file, as a comprehensive report should be). You will find a handy online comment form there too. We would appreciate your reviewing the document and providing a feedback.

The comment period is open until July 18. Comments received before the end of this month can be incorporated into the public draft that comes out in early July.

Completing a CWCS is a requirement of the federal State Wildlife Grants program that provides funds to states to keep wildlife from becoming endangered—every state and territory in the U.S. completing one. The deadline for submission is October 1, 2005 and the CWCS teams and committees have been racing to complete the report before that date.

Please keep in mind that you are reviewing a draft document. It is not complete and will not be complete without your help. In order to meet federal deadlines for completion and submission to the US Fish & Wildlife Service, this version will undergo additional format changes. The final document will have a professional design and layout.

To make your comments most useful please provide specific feedback; give suggestions for improvement in clarity or accuracy of content; or, propose key recommendations that are missing or should be elaborated on. Doing so is much more helpful to the authors than general observations or criticisms. Specific comments about the text should include chapter, page and line numbers (e.g. "chapter 3, page 12 lines 23-24 are confusing."). Please consider addressing the following questions:

"Potential Partners" and "Potential Funding Sources": Each species and habitat strategy in this document includes fields to list both "potential partners" and "potential funding sources." The omission of any logical entities from these fields is strictly due to a lack of time. Please help us by suggesting partners and funding sources.
Don't forget: the CWCS Conservation Partner Review Meeting at Vermont Technical College is this Friday June 24. It will run from 9:30am-12:00pm. The agenda and driving directions are posted below. Please, take a moment now to let me know whether you or are coming or not and the number of people from your agency or organization will join you.

Conservation Partner Meeting Friday 6/24/05
Old Dorm Lounge at Vermont Technical College, Randolph, VT
Agenda
9-9:30 Registration, coffee
9:30-9:40 Welcome - Commissioner Laroche
9:40-9:55 the Future of Wildlife Conservation
9:55-10:25 Vermont's CWCS report (process and recommendations)
10:25-10:35 Break
10:35-noon Questions & Comments

Directions to the Vermont Technical College:
-Take I-89 to exit 4.
-From the Exit 4 ramp, turn onto Rt. 66 heading uphill away from McDonalds. Proceed 3/4 mile to intersection at top of hill. -Drive straight through the intersection to access campus from main entrance.
-Look for signs to the Old Dorm Lounge

Public Meetings: CWCS Public Meetings are scheduled for July 12 (Montpelier) and July 14 (Manchester) and will run from 7:00pm to 8:30pm. I urge you to join us there and to encourage your members to attend. You are welcome to set up a display or bring literature about your organization to the public meetings. Just let me know ahead of time so we can arrange for space. If you can't attend but want to provide me with materials to display, please mail a packet to me at the address below or give it to me at the meeting next week.

Thank you and happy reading.

Sincerely, Jon

Hey! My email address changed on 6/6/05.
It's now --> jon.kart@state.vt.us
Please update your address book. Thank you.

Wildlife checkup

Vermont is part of a major national project to find out what is needed to keep America's wildlife healthy.

This complex and important endeavor, with a deadline of October 2005, has biologists, sportsmen, ecologists, conservationists, and wildlife experts working together to develop a comprehensive blueprint for effective conservation programs across the United States.

Led by the Vermont Fish and Wildlife Department, the Vermont team is supported by a significant federal contribution, the State Wildlife Grants program, which has a goal of preventing wildlife from becoming endangered. Vermont has received more than $2.5 million in grants since the program began in 2001, but many of the participants have volunteered countless hours to be part of this pioneering wildlife inventory.

Next fall, when the work has been completed and the public has had a chance to review draft findings, Vermont will have its first "comprehensive wildlife conservation strategy," a long-range vision for conserving the state's wildlife, from the lowly woodland vole to the catamount.

This effort is in refreshing contrast to recent federal initiatives that have seriously undermined entrenched environmental policies such as the Clean Air Act. It is the kind of positive and innovative work that enthuses scientific experts as well as the average Vermonter who respects and admires the state's wildlife.

Very little is known about many of the species being studied, says Jon Kart, coordinator of Vermont's wildlife checkup. But even the smallest insect can play an important role in the ecosystem. Plants are also being studied to provide the most complete picture possible.

Six teams of experts looked at species that have declining populations, are potentially threatened or are virtual unknowns to scientists. The goal is to identify "species of greatest conservation need" and to identify habitats, key threats, the research needed to increase knowledge about them and strategies to conserve the species. A broad-based review team from 60 agencies and organizations will distill the information and provide a "reality check" before recommendations are made for the public to review in the spring.

A preliminary look at the list of species with the greatest conservation need in Vermont suggests there are about 130 vertebrates, including birds, mammals, amphibians and reptiles, 120 invertebrates, and about 400 plants that need special attention.

The list includes bobcat, bald eagle, common nighthawk, salmon, lynx, martin, a number of bats, barn owl and even mountain lion, or catamount. Kart says
catamounts have existed in Vermont, but there have been no documented findings of them in some time.

"If we can get to the species before it becomes threatened, we have many more options to conserve them and it is much cheaper," Kart said in an interview Thursday.

Vermonters take conservation seriously, not only because they have an affinity for the natural environment they grow up in, but because they benefit from it economically. About $386 million is spent on wildlife-based recreation in Vermont every year, according to a 2001 survey by the U.S. Fish and Wildlife Service.

Once the conservation strategy is complete, stable federal funding will be needed to follow up on the recommendations. Vermont's congressional delegation has been supportive and must continue to press for this allocation. The state will also be asked to contribute, possibly through investing in conservation programs or providing technical and financial assistance to the landowners who own about 85 percent of Vermont's land. These property owners might have the will, but not the money or expertise to preserve their natural areas.

It will require a partnership and an investment. A healthier future for America's wildlife is worth it.

State compiling wildlife inventory

December 30, 2004

By Sky Barsch Times Argus Staff

WATERBURY – In an effort to avoid emergency recovery programs, Vermont wildlife specialists are using federal funds to survey and plan for the protection of creatures that might otherwise be headed for the endangered species list.

Vermont's Fish and Wildlife Department, with the help of federal funding and more than 60 agencies and organizations, is compiling an inventory and plan for the state's animals most in need of conservation, according to Jon Kart, comprehensive wildlife conservation strategy coordinator for the department. The list, called the Comprehensive Wildlife Conservation Strategy, will include what experts believe are the best management practices for more than 200 animals, from lynxes and silver-haired bats to southern bog lemmings and American bitterns. The study looks at plants as well.

The goal is to list the mammals, fish, reptiles, amphibians, birds, invertebrates and insects that are rare or whose populations are declining, and to identify and implement conservation methods before the creatures become so rare that restoring populations is expensive and potentially not possible.

The program is funded by the State Wildlife Grants program, a federal source that aims to survey and protect animals that aren't on the endangered species list and those that aren't typically hunted or fished, according to Kart.

"It's so much cheaper to help something when it's in good shape than to provide triage," Kart said. "That's probably the main reason Congress was interested in enacting this legislation."

Vermont has been eligible for a total of $2.5 million since the program's inception in 2001, and that money has gone to numerous habitat restoration and conservation programs, Kart said, including studying and restoring Bicknell's thrush, osprey and tiger beetles, as examples.

The state is required to complete a Comprehensive Wildlife Conservation Strategy in order to receive the grant funding and must provide a match with state funds, donations and funding from other organizations.

Though the strategy inventory is a requirement of the federal program, Kart indicated the chance to complete the inventory as an exciting opportunity rather than a burden.

"This is the first time this has ever been done. No state has done anything like this. It's all on uncertain territory. We're trying to do this with wildlife we know very little about. It's an incredible exploration," he said.

So far, teams of biologists, ecologists, conservationists and sportsmen and women have identified about 130 vertebrates, including mammals, birds and fish, and more than 120 invertebrates, including insects and mussels, as in greatest need of help. These include martens, shrews, voles, eastern darters, Atlantic salmon, spotted turtles, Western chorus frogs and different species of mayflies.
"They've all been identified," Kort said of the animals in need of conservation. "We go from peregrine falcons, which we know a lot about, to little (woodland) voles, a rodent we only have historically maybe 50 records of them. There's only 50 of those and we don't know, are they very rare in the state? Or are they everywhere and people just didn't look?"

Kort said the Comprehensive Wildlife Conservation Strategy has many benefits. With such a large number of wildlife experts putting their heads together, Kort hopes that the inventory will allow all individuals and organizations who are interested in conservation to be on the same page. Experts are trying to figure out what conditions are adversely affecting Vermont's wildlife. Threats may include a lack of contiguous forest, competing exotic species, or an uncontrolled harvesting by people.

The Conservation Strategy also aims to provide a science-based foundation for understanding the issues involved in addressing wildlife needs, allow conservation actions to be more proactive and less reactive, allow conservation actions of agencies, landowners, interest groups, conservation organizations and others to be coordinated so that they are more cost-effective and produce cumulative benefits and allow existing programs that provide incentives or technical assistance to private landowners for voluntary actions to conserve natural resources on private lands to be used more effectively, among others.

The final strategy, subject to public comment and federal approval, will likely be an electronic document the public will be able to access, Kort said. That way, an individual who is interested in property improvement for wildlife habitat could access the document and get the most comprehensive data available on land management practices.

Vermont is not alone in this mission. The 49 other states and several territories are participating in the conservation program as well, Kort said. Federal money is awarded based on a formula that takes into account a state's size as well as its population.

Kort said he is in frequent contact with those working on the same project in other states, to see what sort of management plans can be implemented regionally.

Field work will continue in the spring, and a draft of the Comprehensive Wildlife Conservation Strategy is due out sometime next year.

Study focuses on health of Vermont's wildlife
Steve Zind

COLCHESTER, VT (2004-12-31)

(Host) The Vermont Fish and Wildlife Department is involved in a nationwide effort to take stock of country's wildlife. Officials say when the work is completed it will be the first time that all of the state's animals, plants and insects have been surveyed.

VPR's Steve Zind reports.

(Zind) Biologists, sportsmen and conservationists have spent a lot of time studying Vermont's game animals and endangered species. But Jon Kart of the state Fish and Wildlife Department says most of the state's wildlife doesn't fall into those categories.

(Kart) "The other 95 percent of the wildlife in the state has been virtually ignored due to lack of funds, due to lack of biologists to work on them and manage them and care for them. Finally, just a few years ago, Congress came up with the state wildlife grant program and this program provides money for that other 95 percent."

(Zind) The federal government is requiring states to devise what's called a Comprehensive Wildlife Conservation Strategy. Kart heads up Vermont's effort. He's been working with representatives from more than 60 groups to gather information about everything from crawfish to black bears.

The idea is to alert officials to species that are in trouble before they reach a critical point. Kart says the study is designed to find out which species are healthy and which are in decline, and to identify threats to species and strategies to conserve them. He says it's clear that for many species declining habitat is clearly an issue.

(Kart) "In the Champlain Valley we have a fraction of the clay-plain forest we once had. And the number of species that might live there, well we're just starting to figure out because there's maybe 10 percent left. I guess the main piece is, we're finding key habitats that need attention."

(Zind) Kart says the biggest surprise so far is how little we know about many species. He says once every state has completed its survey, scientists, policymakers and the public will for the first time have a big picture idea of the health of the nation's wildlife.

(Kart) "And really be able to show what do we need to do to preserve wildlife in America. And that's going to be a great moment."
(Zind) Kart says a draft of Vermont Comprehensive Wildlife Strategy should be complete by spring when the state will hold public hearings on the plan. But the work will be ongoing because Kart says there's still much to learn about Vermont's wildlife.

For Vermont Public Radio, I'm Steve Zind.

Sample Newsletters
Commissioner’s Greeting

In recent years, state fish and wildlife agencies, all across the country, have been the beneficiaries of new federal dollars for conservation through a program called State Wildlife Grants. One of the requirements of accepting these new dollars is that each state agency must complete a Comprehensive Wildlife Conservation Strategy by October 1, 2005. This newsletter, which we anticipate publishing twice per year, will be one tool to assist with communicating about the progress of developing the Strategy.

These new dollars offer a historic opportunity to fund new research, inventory, and management actions for species of greatest conservation need, as mandated by the funding legislation. This is consistent with the Vermont Fish & Wildlife Department’s broad mission and provides much needed sustainable funding. In this first issue of the newsletter, we highlight some of the exciting new initiatives being funded with the help of State Wildlife Grant dollars.

Sincerely,

Wayne A. Laroche

Vermont is home to a vast array of fish and wildlife species, including mammals, reptiles, amphibians, birds, fish, and insects. Many of these species are not traditionally harvested through regulated hunting, fishing or trapping programs. These species account for more than 95 percent of the fish and wildlife in Vermont. Some of these species are declining or considered at risk. Over 200 species are endangered, threatened or rare.

For several years, the States have asked the U.S. Congress to provide adequate, reliable annual funding to help reverse the decline and prevent species from becoming endangered. Congress responded by providing one-time state funding in the form of the Wildlife Conservation and Restoration Program (WCRP) in 2001. Congress then provided additional funding for the next three years through the State Wildlife Grants (SWG) Program.

With this new influx of monies, the Vermont Fish & Wildlife Department will begin laying the groundwork for proactively managing our species of greatest conservation concern. Over the next four years, between $2 and $2.3 million will be invested to support a variety of projects that will fill important knowledge gaps involving species of conservation concern, measure public opinion on
fish and wildlife conservation issues, and significantly contribute to the development of Vermont’s Comprehensive Wildlife Conservation Strategy.

By developing a Comprehensive Wildlife Conservation Strategy for Vermont, the department has the opportunity to incorporate the management of all species into existing programs, build valuable partnerships, and identify conservation threats and opportunities that will affect our wildlife management efforts. We hope this will help secure long-term funding for the important job of conserving Vermont’s fish and wildlife heritage. In the following pages you will learn about some of the projects we are initiating to fulfill our mission to conserve Vermont’s fish and wildlife, their habitats, and natural communities for the people of Vermont.

**Fish and Wildlife Species and Habitat Inventories**

Several projects funded through the State Wildlife Grant program will provide information on species abundance and distribution as well as the location and condition of suitable habitats. We will use the information gathered to determine the status of populations, identify the threats to sustaining these populations, and prioritize effective conservation strategies. The following are some highlights of those projects.

The **Montane Spruce-Fir Forest** natural community will be inventoried. The Montane Spruce-Fir Forest is a dominant natural community above 2,500 feet elevation in Vermont. This forest and associated subalpine and alpine communities provide important wildlife habitat for many species, including Bicknell’s thrush, a bird of special concern in Vermont. This project will identify most of the state’s examples of Montane Spruce-Fir Forest. The ecological integrity and habitat value of each example will be evaluated through aerial flights, maps and site visits. A newly developed ranking system will be used to evaluate the ecological significance of each example.

Although this community is not under threat of typical residential sprawl, it may be threatened by acidic precipitation and development associated with ski areas and ridgeline wind towers. Therefore, the information gathered will improve the department’s ability to work with the public and landowners to make sound decisions on land and habitat conservation and management planning.

A recovery plan for Vermont’s endangered **spruce grouse** population will be developed. This species is restricted to 25 square miles of Lowland Spruce-Fir Forest in northern Essex County.

Although the population appears to be stable if not slightly increasing, there is only one isolated population. Reintroducing and re-establishing a second subpopulation of spruce grouse to a former portion of their range in Vermont could help secure the long-term viability of the population.

The department will capture and release a minimum of 60 spruce grouse (40 percent adults and 60 percent juveniles) in Victory Basin. The captured spruce grouse will originate from Quebec, Ontario, New Brunswick, or Maine. Genetic investigations will help determine which source, if any, would be the most appropriate. Following the release of the birds, we will conduct annual surveys to monitor and determine the project’s success. A number of the released birds also will be radio-tagged. This will enable us to monitor bird location throughout year and provide information on survival, home range size and dispersal movements.

The **lake sturgeon**, once abundant in Lake Champlain, is now listed as endangered. A survey program was initiated in 1998 to determine if sturgeon are still present, and to gather data on relative abundance, age and size structure of any remaining population. The survey targeted historic spawning sites in the Winooski and Lamoille Rivers.

The results of this sampling effort were positive, sturgeon still exist in Lake Champlain. However, sampling indicated the need to expand our

*(Continued on page 3)*
survey to include other historic spawning sites and other tributaries to the lake.

With the new State Wildlife Grant funding, we plan to expand department efforts to attempt sturgeon egg collection in Otter Creek as well as continue egg sampling on the Lamoille and Winooski Rivers. Biologists also will attempt to collect drifting sturgeon larvae. Results from this project will improve our information on the population size, reproductive success, and the age and size structure of the lake sturgeon found in Lake Champlain. This information will be vital for developing restoration strategies for the recovery of Lake Champlain's sturgeon.

The timber rattlesnake and eastern ratsnake both have restricted distributions in Vermont, and their continued existence in this state is a conservation concern. The rattlesnake is listed as endangered and the ratsnake is at risk and proposed for threatened status. Traffic, mowing and intentional killing are all sources of mortality. In addition, visitation to sensitive sites, such as denning areas, is believed to negatively impact the rattlesnakes.

With State Wildlife Grant funding we will build on past efforts to monitor and inventory rattlesnakes in Vermont. Although the rattlesnake and ratsnake have different life histories, their habitat use and geographic distributions overlap. Therefore, conservation efforts on behalf of the endangered rattlesnake will also benefit the ratsnake.

Through department inventory work we will gain better understanding of species distribution, population health, and how these species use the landscape throughout the year. We will reach out to local citizenry living close to rattlesnake habitat to encourage conservation and gather information about the snakes and threats to their survival. This information also will enable us to develop a recovery plan for these snake species.

Inventorying and documenting the current distribution of turtle species of conservation risk in Vermont is another project. Vermont is home to seven species of turtles that are of a conservation concern. The spotted turtle is state-endangered with only one documented population. The spiny softshell turtle is state-threatened and is found in only two areas of Lake Champlain. The wood turtle, although still widespread, is at risk from a variety of threats, as are the remaining four turtle species. Population isolation, habitat loss, boat and car traffic, nest predators, and the pet trade threaten the survival of Vermont's turtle species.

The department will monitor selected turtle species (spotted, spiny softshell, and wood turtles) to gain knowledge of their life history and habitat needs. Using a variety of techniques biologists will gather information on populations, necessary habitats, distribution, and threats. This information will help in maintaining and enhancing vulnerable turtle populations. The department also plans to draft recovery plans for spiny softshell and spotted turtles.

Currently the department is in the process of developing a statewide bat conservation and recovery plan. Vermont is inhabited by nine species of bats, six of which are known to hibernate in the state and eight of which are thought to raise young here. Of these nine, only one is ranked as demonstrably secure. The remaining bat species are ranked as uncommon, very rare, federally endangered or state threatened.

While developing the plan, it became evident we needed more information on the current status of several bat species. Increased surveying and inventorying efforts will focus on the highest priority species. We will conduct spring, summer and fall surveys to determine female Indiana bat distribution in Vermont. We will survey for the small footed bats, eastern pipistrelle, and Vermont's migratory bat species—red, hoary and silver-haired bats. Inventories will include known and potential winter hibernating sites (hibernacula). We will document big brown and little brown maternity sites (sites used by bats for having and rearing young). We also will compile existing records of bat surveys to develop a comprehensive bat species inventory by town, region and other attributes.

This distribution and habitat use information will help in developing sound management and conservation strategies for the bats.
strategies. These strategies may include: forest management activities that conserve habitats used by Indiana bats for feeding and rearing their young; strategies to maintain man-made structures, such as barns and bridges, for roosting habitat; and pest control procedures that minimize bat mortality.

In Vermont, ten of our eighteen fresh water mussel species are on the state’s endangered and threatened species list and several others are considered rare. Funds provided through the State Wildlife Grant program will finance inventory and monitoring efforts on rivers around the state to determine the status of selected freshwater mussel species.

The mussel species targeted for investigation include state or federally listed species, or species of special concern that need more information to determine their current status. These include the dwarf wedgemussel, brook floater, elktoe, and a group of mussels species that occur within portions of Lake Champlain and its major tributaries below the river’s first major waterfall. Seven species in this group are listed as state threatened or endangered.

Information collected from these inventory and monitoring efforts will be used to develop conservation priorities and strategies to achieve mussel recovery goals. Ongoing survey and monitoring efforts will aid in tracking population trends statewide, help refine recovery strategies, and determine whether recovery goals have been met.

Two citizen-based inventory projects receive funding through the State Wildlife Grant program. They are the Vermont Butterfly Atlas and the Vermont Breeding Bird Atlas. The benefits of these “citizen science” projects are many.

The projects engage a large number of Vermonters in collecting and reporting species and habitat information. Not only do these volunteers collect information important for conservation, but they also make these extensive inventorying efforts possible, due to the scope of these projects.

The Vermont Breeding Bird Atlas is a comprehensive statewide mapping project. It is directed by the Vermont Institute of Natural Science and financially supported by the Vermont Fish & Wildlife Department’s State Wildlife Grant program. In the spring and summer of 2003, over 300 volunteers took to Vermont’s countryside to begin a five-year project to gather information about birds breeding in Vermont. The atlas is providing needed information on some of Vermont’s rarest birds, a comparative look at the distribution of all wild birds, and some abundance data. This information will enable the bird conservation community to detect changes in bird distribution and number, identify areas of concern, and aid in conservation planning.

The State Wildlife Grant funds also are providing support for work to evaluate aquatic habitats. Temperature is a significant factor in determining a stream’s fish community. This project will test the effectiveness of using stream temperature data to address the issues of land use, the need for adequate riverbank vegetation (riparian zones) and the benefits of dam removal.

Using the Mad River as a test site, this project will analyze temperature data to provide a variety of information. Some of this information includes: measuring the effect of shading by...
determining water temperature differences between the forested upper river and the open agricultural section downstream; demonstrating the effects of the Moretown dam on downstream temperatures; using a temperature model to explore “what if” scenarios for temperature changes that would result from establishing a certain type of riparian zone over a certain length of river; and assessing the usefulness of temperature modeling for future applications and conservation planning.

Data from the Mad River will be used to explore applications that can be used statewide. And, it will add support to our habitat restoration efforts by providing actual numbers to demonstrate the relationship between land use and stream temperature.

Another project involves revising and updating the current **ranking system for natural communities**. In Vermont, natural communities are recognized as one of the primary tools for describing and mapping state lands. They also are a tool used for making land-management decisions regarding wildlife habitat, rare species and recreation values.

The rarity of natural communities is ranked based on how frequently they occur and the total area the community type occupies. The quality of natural communities also is ranked based on an assessment of the size, the current condition of the natural community, and the condition of the surrounding landscape. The new ranking specifications will weight these three quality factors and will be based on a review of current scientific literature. This new system will “fine-tune” the current system by improving objectivity in the ranking process.

This new system will provide an accurate, objective, reliable, and practical tool for evaluating and ranking the ecological significance of natural communities. State agencies and private landowners will benefit from this new system when making conservation and management planning decisions.

**Conservation Planning Assistance**

The State Wildlife Grant program also supports projects focused on providing conservation planning assistance to government, local and regional land use planning, and conservation organizations. The conversion of the department’s existing database for tracking rare species and significant communities to the new **GIS-based Biotics data system** is one example.

The Vermont Fish & Wildlife Department maintains a database that includes 6,000 occurrences of rare species and significant communities. Other databases include information about deer yards, bear habitat, wildlife road crossings, and other information. The new Biotic database system will track and map this information more efficiently and be more user-friendly. Converting to this database system will increase the availability of up-to-date information to biologists, planners and the general public. It will improve customer service and provide better information for conservation planning and technical assistance to government, conservation organizations and interested citizens.

The new State Wildlife Grant inventorying and monitoring projects will generate a great deal of new data vital for conservation planning, species management and regulatory review. Some of these projects will add more than 100 new or updated occurrence records to our Biotics database. In addition, other ongoing projects and outside sources also generate data for inclusion in our database.

To maintain a current database and to improve assistance to local, state and region wide projects and plans, we hope to use State Wildlife Grant funding to add several specialists to our staff. These specialists will create and update GIS coverages for rare animals, critical wildlife habitats and natural communities for conservation planning, and provide technical information on rare species, significant natural communities and critical habitats from the department’s database to government and non-government planners, researchers and landowners.

The State Wildlife Grant funds also will provide the financial support to employ a wildlife biologist to assist in **town and regional conservation planning**. This person will be responsible for assisting interested groups in applying the processes and information presented in a conservation planning manual recently developed by the department.

This guidance manual, funded through the Wildlife Conservation and Restoration Program, was written to help town planning commissions and conservation commissions develop land use plans that recognize the... (Continued on page 6)
conservation needs of fish and wildlife resources. The biologist will work directly with interested towns, regional planning commissions and other interested conservation organizations, and assist them in using the manual. The position will provide a centralized expert for people involved in planning to contact for help and ensures that the assistance provided is consistent and based on contemporary science and information.

This position and program will foster a greater appreciation and understanding of fish, wildlife and biological processes within Vermont communities. It also will enhance the department’s abilities to further fish and wildlife conservation on private lands throughout Vermont.

Fish and Wildlife Research

Two projects funded by the State Wildlife Grant program are research projects. One research project will investigate the population dynamics of the Indiana bat in the Champlain Valley. This State Wildlife Grant is partially funding the second phase of Indiana bat research at the University of Vermont (UVM) Cooperative Fish and Wildlife Unit. The research will increase our understanding of maternity colony characteristics and activities as well as habitat needs.

This project will identify and characterize maternity and alternate roost trees; document the use of roost trees over the years; determine how many individuals are using the identified trees; and analyze landscape characteristics of maternity roost sites. The research also will identify habitat characteristics associated with Indiana bat roosting and feeding activities. The information collected will help in refining our Indiana bat conservation planning efforts and programs.

The other research project, also being conducted at UVM, involves determining the influence of egg-oiling on the population dynamics of double-crested cormorants. In 1999, the department began applying corn oil to cormorant eggs on Young Island to manage population size. Although the oiling nearly eliminated all cormorant reproduction on Young Island in 1999 and 2000, the overall impact on the size and distribution of the cormorant population on Lake Champlain was unclear. Patterns of dispersal suggest egg oiling causes cormorants to abandon the Young Island colony and move to alternate locations.

Current models for predicting cormorant population growth assume no movement between the colonies. However, research suggest a model that incorporates movement between colonies is needed to accurately predict and assess changes in the overall cormorant population size and distribution in response to oiling practices.

This State Wildlife Grant project will develop a population growth model for cormorants on Lake Champlain that includes movement of cormorants among colonies. This model, known as a metapopulation model, will predict growth of individual cormorant colonies given specific demographic rates (rates of birth, death, birds joining and birds leaving a colony) for each colony. It also will predict the growth and persistence of the Lake Champlain population. The model will allow managers to develop a cormorant management plan based on predicted growth of each colony on Lake Champlain in response to different management scenarios.

What’s Next?

Although the State Wildlife Grants program funding is short-term, the projects it is funding will greatly enhance our knowledge and understanding of those species of concern. It will help establish a means to proactively manage these species through the development of a Vermont Comprehensive Wildlife Conservation Strategy.

This Strategy will outline the status, threats, and conservation strategies needed to maintain Vermont’s native fish and wildlife species. It also will serve as a roadmap for Vermont’s fish and wildlife conservation community to work toward achieving its many goals and interests in a comprehensive approach that ultimately conserves all fish and wildlife species. In the months to come, we will use this newsletter to report on the progress of the different projects as well as the Strategy’s development.
Vermont’s Wildlife Get a Check-Up

An unprecedented evaluation of Vermont wildlife is underway. Spearheaded by the Vermont Fish & Wildlife Department, biologists, ecologists, conservationists and sportsmen representing more than 60 agencies and organizations have teamed-up to give Vermont’s wildlife a check-up.

From black bear to yellow-bellied sapsucker, red mulberry plant to blue-spotted salamander, and silver redhorse sucker to pink heelsplitter mussel, experts are assessing the health of wildlife populations and developing prescriptions for healthy wildlife futures.

Next fall, when their work is complete, Vermont will have its first Comprehensive Wildlife Conservation Strategy (CWCS). It will be a strategic vision for conserving the state’s wildlife, one that all conservation-minded agencies and organizations can get behind.

Development of CWCS is driven by the State Wildlife Grants program (SWG), a federal funding program to prevent wildlife from becoming endangered. Since SWG’s inception in 2001, Vermont has received more than $2.5 million in conservation dollars. To remain eligible for State Wildlife Grants states must complete a CWCS by October 2005.

Vermont is home to 42 species of reptiles and amphibians, 63 mammals, 94 fish, 235 birds, more than 2,000 plants and many, many more insects, mollusks and other invertebrates. Assessing the status of each of these species is a huge task requiring an effort of unmatched cooperation.

Continued on page 5
Creating Vermont’s Comprehensive Wildlife Conservation Strategy

The Comprehensive Wildlife Conservation Strategy (CWCS) is an exciting opportunity to shape the future of Vermont’s fish and wildlife conservation. Congress charged state fish and wildlife departments with leading the CWCS development, but Congress expects the states to solicit help, advice and expertise from other state and federal agencies, conservation and sportsmen’s organizations and the general public. To this end, six technical and three coordination teams were created to ensure comprehensive scientific input into the CWCS.

What will the Comprehensive Wildlife Conservation Strategy look like? The primary purpose is to target species of greatest conservation need. However, the plan will address the full array of wildlife and habitats—taking advantage of good work already done and filling in knowledge gaps. Congress left much of the design of the CWCS up to each state, but Congress does require eight elements be included in every Strategy. Those elements are:

1. Status Check: Identify the distribution and abundance of wildlife species.
2. Habitat Check: Assess locations and condition of habitats that are vital to conserving species.
3. Key Threats: Describe problems that may harm species and priority research needs.
5. Monitoring: Identify steps for keeping an eye on species, habitats and conservation actions.
6. Review: Assess the CWCS at intervals not to exceed 10 years.
7. Coordination: Involvement of federal, state, local agencies and Indian tribes that manage lands or programs affecting wildlife.
8. Public Participation: An essential element of developing and carrying out plans.

You can find periodic updates and background materials on the development of the Comprehensive Wildlife Conservation Strategy at the department’s CWCS website www.vtfishandwildlife.com/swg_home.cfm. A draft of the CWCS will be posted on the website in April 2005, and public meetings will be held after that. If you want additional information, or if you have comments or suggestions, contact CWCS Coordinator Jon Kart at jon.kart@anr.state.vt.us or 802-241-3652.

State Wildlife Grants (SWG) provides federal dollars to every state and territory to support conservation aimed at preventing wildlife from becoming endangered. To make the best use of the State Wildlife Grants program, Congress charged Vermont and all other states with developing a statewide Comprehensive Wildlife Conservation Strategy (CWCS) by October 2005. This newsletter highlights the development of the CWCS and the essential conservation efforts supported by State Wildlife Grants dollars.

Why is SWG essential to wildlife conservation in Vermont? State fish and wildlife agencies have a great record of success restoring and conserving wildlife. Hunter and angler license fees and taxes on hunting and fishing equipment have funded the bulk of this work. As a result, much of the conservation efforts have focused on game species. There has always been a serious lack of funding for those species that are not hunted or fished. SWG funds will help Vermont and other states address the needs of those species for which limited funding has been available. In many cases, SWG funded conservation projects represent the first time a species or habitat has been examined or surveyed by professionals in Vermont.
The State Wildlife Grants (SWG) program plays a vital role in efforts to conserve Vermont’s wildlife. In many cases SWG-funded projects represent the first time species and habitats have been examined, studied or surveyed by experts. Since 2001, SWG has funded more than 40 programs in Vermont including conservation research and recovery planning, terrestrial and aquatic habitat assessments, and the inventory and monitoring of rare and uncommon species. Here is a list of current and ongoing SWG-funded projects.

- Bobcat habitat use and habitat assessment.
- Improving road/stream crossing structures to aid fish and other aquatic organisms.
- Statewide all-bird inventory (atlas).
- Statewide butterfly inventory (atlas).
- Lake Champlain deepwater forage fish inventory.
- Inventory for rare and uncommon non-game fish such as sculpin, stonecat, several species of redhorse, shiner and darter.
- Comprehensive inventories of State Wildlife Management Areas for amphibians, reptiles, invertebrates, non-game fish, birds, and mammals.
- Inventory and recovery planning for several species of rare tiger beetles.
- Public workshops to reduce the spread of invasive non-native fish sold as bait fish.
- Lake sturgeon inventory and recovery planning.
- Muskellunge inventory and recovery planning.
- Stream temperature and habitat improvement.
- Bicknell Thrush inventory and habitat assessment.
- Research on the Black-throated blue warbler.
- DNA-based fish health research.

Here Kitty Kitty
by Jon Kart

Anyone who’s ever looked for a home knows how difficult it can be to find the right place. Choices are rarely simple. Would you accept a smaller living room if the view was great? What if the house were close to work? How close do shopping or schools need to be? How much privacy do you want? Clearly, finding the right place is a blend of many factors.

We’re not alone. Many wildlife species face the same questions. Though some species are quite easy to satisfy—you can find squirrels in almost any forest, woodlot or suburban yard—others are more discriminating.

The bobcat is in the latter category. Although bobcats are found throughout Vermont, it is an elusive animal with special habitat needs that aren’t fully understood.

It is believed a combination of steep rocky ledges, wetlands, and large undeveloped tracts of land connected by corridors are important to the future of bobcats in Vermont. However, no one is sure how bobcat reproduction and survival are impacted by the loss or degradation of these habitats. As development pressure increases in Vermont, bobcat habitat might be lost or fragmented.

Wildlife biologists will tackle this home design puzzle using funding from the State Wildlife Grants program. University of Vermont Cooperative Extension Unit, in cooperation with the Vermont Fish & Wildlife Department, will evaluate how ledge habitat, landscape fragmentation, road densities, and increasing human densities affect bobcat habitat use, bobcat birth rates, and bobcat survivability.

Ten to twenty bobcats in northwestern Vermont will be fitted with radio collars. The high-tech collars will record time, date, level of activity, and temperature every five hours. Biologists will be able to track the bobcats’ movements over a two-year period. The movements will be mapped along with habitat information collected from on-the-ground surveys and remote-sensing geographic information systems (GIS) data.

The end product will be a picture of how bobcats move through their territories and should reveal the requirements of healthy bobcat communities. This will allow land and wildlife managers to identify and manage important bobcat habitat, ensuring bobcats will be around in Vermont for future generations to enjoy.
Imagine you are a brook trout. You pride yourself with being a strong swimmer and a pretty good leaper. You can scale steep brooks and shimmy through log jams. But for the life of you, you can't leap three feet up into that culvert and swim 150 feet through ripping stream flow to reach that primo spawning habitat upstream. You can sense it's there—you can almost smell it. But it's beyond reach.

Such is the case for many fish and other aquatic organisms throughout Vermont's waters. There are countless barriers, such as culverts and dams that prevent wildlife from moving up and down Vermont's streams and rivers. Culverts in particular pose a daunting challenge, as there are literally thousands of them in Vermont's landscape with the potential of more being installed every day as Vermont continues to develop.

Poorly designed or installed culverts can lead to:

- direct loss of aquatic habitat
- loss of resident aquatic populations, including fish, salamanders, mussels, and other stream-dwelling animals
- loss of access to critical spawning, rearing, feeding or refuge habitat, especially for Vermont's trout species, walleye, fallfish, smelt, and other fish known to move seasonally

- altered aquatic community structure
- altered genetic composition of aquatic populations

Though Vermont road owners have legal obligations to design and install stream-crossing structures that do not hinder the movement of aquatic organisms, thousands of these structures are deficient. This is partly due to lack of sufficient understanding of aquatic organism passage needs, both in the academic and management realms. There have been many recent gains, however, elsewhere in North America in understanding the needs of aquatic organism passage at culverts. Bringing this knowledge and expertise to Vermont to better design, install and maintain stream crossing structures is essential to restoring aquatic habitat connectivity and aquatic organism movement in Vermont's rivers and streams.

With funding from the Wildlife Conservation and Restoration Program (the precursor to State Wildlife Grants program), and in partnership with the Vermont Agency of Transportation, the Vermont Fish & Wildlife Department is developing technical criteria and guidelines for installation and management of stream crossing structures. The department also will provide technical training and assistance to road managers, regulators, fisheries biologists and others. The goal of the project is to improve aquatic organism passage at road crossings over streams and enhance habitat connectivity in Vermont’s waters.

The Hydro-Acoustic Project isn't the name of a band. However it will keep Bernie Pientka out late at night listening attentively. Bernie is a fisheries biologist with Vermont Fish & Wildlife Department (VFWD) and in this case he'll listen for fish—not Phish.

Bernie is interested in the forage fish community of Lake Champlain. Forage fish play a key role supporting much of the lake's food web. Most food webs resemble pyramids, with lots of species at the bottom eaten by fewer species at the top. However, rainbow smelt is the single dominant species of the deep-water fish community in Lake Champlain. If the smelt population were to decline, due to disease, pollution, the arrival of an invasive species or some other reason, much of the rest of the pyramid of larger fish could crash. In other words, this little three-ounce, iridescent fish with a pale green back and purple, blue and pink sides plays a pivotal role in the lake's ecosystem.

Clearly, keeping tabs on the smelt population is important, but counting fish in the sixth largest lake in the U.S. is no easy task. So, with financial
Wildlife Get a Check-Up
Continued from page 1

The Vermont Fish & Wildlife Department has teamed up with local, state and federal agencies and non-profit organizations who help conduct the assessments and provide oversight. Our Conservation Partners are listed on the right.

Six species teams spent several months identifying Vermont’s “species of greatest conservation need” using criteria such as species rarity, vulnerability to habitat fragmentation or loss, and threat by exotic plants or animals. The list is available on the Vermont CWCS website: www.vtfishandwildlife.com/swg_home.cfm.

The species teams are Bird, Fish, Invertebrate, Mammal, Plant, and Reptile and Amphibian. Now, these teams are assessing habitat and identifying significant threats to the species. They also will develop conservation strategies to conserve these species and their habitats.

An integration team will then combine the work of the six species teams into an integrated strategy and develop monitoring plans to track wildlife progress and measure the effectiveness of the conservation strategies.

A conservation strategy review team will review the CWCS. They will make additional strategy recommendations, help gather public input, and work with the integration team to finalize the Comprehensive Wildlife Conservation Strategy.

A draft of the CWCS will be available for review and a public comment period will occur during the spring of 2005. Wildlife enthusiasts, landowners, businesses and the general public are encouraged to track and take part in CWCS development. More information can be found on the Vermont CWCS website: www.vtfishandwildlife.com/swg_home.cfm.

Conservation Partners in Vermont’s Comprehensive Wildlife Conservation Strategy

The development of Vermont’s Comprehensive Wildlife Conservation Strategy is a project for all Vermonters. The Vermont Fish & Wildlife Department is working with dozens of organizations representing diverse interests who have joined forces to help wildlife, including:

- American Chestnut Foundation
- Association of VT Conservation Commissions
- Audubon Vermont
- Burlington Electric Department
- Center for Woodlands Education
- Chittenden County Regional Planning Commission
- Connecticut River Watershed Council
- The Conservation Fund
- Consulting Foresters Association of Vermont
- Ducks Unlimited
- ECHO
- Endangered Species Committee
- Fairbanks Museum & Planetarium
- Forest Watch
- Green Mountain National Forest
- Hunters, Anglers & Trappers Association of Vermont
- Keeping Track, Inc.
- Lake Champlain Committee
- Lake Champlain International, Inc.
- Lake Champlain Land Trust
- Lake Champlain Walleye Association
- Lewis Creek Association
- Marsh-Billings-Rockefeller NHP
- National Wild Turkey Federation
- National Wildlife Federation
- Natural Resources Conservation Service
- Nature Conservancy
- New Haven River Anglers Association
- North Country Environmental & Forestry
- Ruffed Grouse Society
- Ryegate Power Station
- Sierra Club
- Society of American Foresters
- Smugglers Notch Resort
- Sportsmen Inc.
- US Fish & Wildlife Service, Lake Champlain Fish & Wildlife Resources Complex
- US Fish & Wildlife Service, Missiquoi NWR
- US Fish & Wildlife Service, Nulhegan Basin Division
- UVM School of Natural Resources
- UVM Botany Department
- VT Agency of Transportation
- VT Association of Snow Travelers
- VT ATV Sportsman’s Association, Inc.
- VT Bird Tours
- VT Cooperative Fish & Wildlife Research Unit
- VT Coverts
- VT Department of Environmental Conservation
- VT Department of Forests, Parks & Recreation
- VT Farm Bureau
- VT Federation of Sportsmen’s Clubs, Inc.
- VT Fish & Wildlife Board
- VT Forest Products Association
- VT Institute of Natural Sciences
- VT Land Trust
- VT Loggers Association
- VT Natural Resources Council
- VT Outdoor Guides Association
- VT Ski Area Association
- VT State Grange
- VT Trappers Association
- VT Woodlands Association
- Wildlands Project
- Representative Steve Adams
- Office of Congressman Sanders
- Office of Senator Jeffords
- Office of Senator Leahy
An Ear To The Water

Continued from page 4

support from State Wildlife Grants, Bernie, Dave Gibson (VFWD), Nick Staats (USFWS), Donna Parrish (VT Cooperative Fish and Wildlife Research Unit) and Lars Rudstam (Cornell University) are designing a lakewide hydro-acoustic survey to track the abundance and distribution of smelt and other forage fish in the lake.

Based on a similar method used in the Great Lakes, sonar (sound waves) is used to “photograph” the fish. Some are then netted to determine the species and their age.

Biologists can then estimate the number and age of fish in the lake. Surveys are conducted at night when the fish are more uniformly distributed, using the department’s 32-foot research vessel.

Tracking changes in abundance of the forage fish community more accurately adds to our understanding of the entire Lake Champlain ecosystem. Data collected will aid biologists in evaluating and responding to changes to the ecosystem, such as the impacts of new invasive species, helping to maintain a balance in a lake so important to wildlife and people.

Rainbow smelt

WON’T YOU LEND A HELPING HAND?

PLEASE DONATE TO THE NONGAME WILDLIFE FUND.

The State Wildlife Grants program makes your tax-deductible gift go much further.

For every dollar we receive for the Nongame Wildlife Fund, we can spend four dollars on protecting and enhancing Vermont’s nongame wildlife and natural communities.

You can contribute to the Nongame Wildlife Fund on your Vermont income tax form, on hunting and fishing license applications, by purchasing a Conservation License Plate, or by direct donations to the Nongame Wildlife Fund, Vermont Fish & Wildlife Dept., 103 S. Main St., Waterbury, VT 05671-0501.

**Good News and Bright Futures**

*by Jon Kart, CWCS Coordinator*

This is a classic story of hard work and cooperation. It’s certainly one to celebrate.

Ospreys, common loons and peregrine falcons—each exciting and fascinating birds—were removed from the State’s Endangered Species List in April 2005. This is the first time *any* endangered species in Vermont has recovered sufficiently to warrant delisting. In the words of John Hall, veteran FWD staffer, “No one thought the recovery programs would be so successful so quickly.”

It wasn’t always this way.

Osprey, loon and peregrine falcon, each evolved over eons to take advantage of their particular niche. But by the mid to late 1900s challenges overwhelmed them.

Among the worst, poorly designed development shredded habitats, pollutants such as lead caused mortality, and eggs were so weakened from pesticides that shells collapsed under the weight of expectant parents. Populations plummeted. Peregrine falcons were gone from Vermont by the mid-1900s. Osprey nesting ceased in the early 1970s. By 1983 only eight breeding pairs of common loons remained in Vermont.

Something had to be done. And it was.

All three species benefited from the...
Nine Great Reasons to Support the CWCS

by Jon Kart, CWCS Coordinator

The Comprehensive Wildlife Conservation Strategy (CWCS) is the largest wildlife conservation planning project ever in Vermont and the nation. Intensive development efforts have been under way since January 2004. With just a few short months until completion, two feelings well up as I review what we’ve accomplished so far: exhaustion and excitement. I’ll spare you the first, but I will share nine exciting reasons to support Vermont’s CWCS.

1. This is an historic effort: this kind of comprehensive endeavor has never been done before in Vermont. Every state and territory in the nation is also developing a CWCS.

2. The goal is to prevent wildlife populations from declining and being listed on the Threatened and Endangered Species List. Keeping common species common means more wildlife to enjoy and fewer regulatory requirements.

3. This is a rigorous review process to determine conservation priorities for species that have previously received little attention.

4. The CWCS asks: What species and habitats are most at risk? What are the risks and threat factors? Most importantly, what are the appropriate actions needed to improve or keep populations from declining? Strategic action is the name of the game. The CWCS will be packed with action recommendations such as: Providing technical assistance to anglers, landowners and/or communities to better manage habitat; creating safer passage over or under roads where they intersect wildlife corridors; and, providing financial incentives for private landowners to protect key habitats.

5. The Vermont Fish & Wildlife Department is working with a broad cross section of Vermonter to create the CWCS. From wildlife experts to sportsmen to other conservationists to industry leaders and state and federal agencies, more than 60 entities have signed on as CWCS Conservation Partners.

6. This effort has emerged through the work of a broad national bipartisan wildlife conservation coalition called Team with Wildlife. The Teaming with Wildlife coalition includes more than 3,000 organizations.

7. The CWCS is not just a planning exercise—the strategies in it will guide the existing State Wildlife Grants program (SWG). Vermont has received almost $3 million in SWG funds since its inception is 2001 and more is expected for implementation.

8. The task of conserving declining wildlife is challenging, but we know success is possible from our history with wildlife conservation successes such as the wild turkey, white-tailed deer, beaver, wood duck, Canada goose, fisher, osprey, common loon, and peregrine falcon.

9. The Comprehensive Wildlife Conservation Strategy and the State Wildlife Grants mark the start of a new era in wildlife conservation, one where we hope to keep common species common.

Your input is needed too. For more information and meeting dates go to the Fish & Wildlife website: www.vtfishandwildlife.com and click on Comprehensive Wildlife Strategy under the Wildlife Programs drop-down menu.
Private Landowners are the Key to Vermont Wildlife Conservation

by Jon Kart, CWCS Coordinator

Some of Vermont’s best wildlife biologists, fisheries biologists, ecologists, botanists, foresters, planners, water quality specialists, hunters, trappers, and conservationists spent much of the past year developing our Comprehensive Wildlife Conservation Strategy (CWCS). From the black sandshell (mussel) to golden-winged warbler, silver redhorse to blue-spotted salamander, these experts are gauging the health of wildlife populations and developing prescriptions for healthy wildlife futures.

When asked about the big picture, how to prevent extinctions and keep common species common, most will tell you “private landowners are the key to wildlife conservation in Vermont.” With 87 percent of the state in private ownership and economic conditions driving the sale and subdivision of much of the state’s forest and farmlands, it’s an astute and challenging reply.

The Fish & Wildlife Department has long worked to address this challenge, but now two federal programs are providing the needed funding to move efforts in new directions. These are the State Wildlife Grants program (SWG), and the Wildlife Habitat Incentives Program (WHIP). SWG funds will be used to implement the CWCS. Expect the CWCS to include many cooperative strategies such as: providing technical assistance to landowners, towns and communities to help them better manage wildlife habitat; financial incentives for habitat management; education programs concerning habitat and species requirements; and strategies for protecting critical habitat resources.

A test program will begin this spring cosponsored by Vermont Fish & Wildlife and Vermont Coverts, a nonprofit group dedicated to encouraging the maintenance and improvement of wildlife habitat on private forestlands. Coverts will serve as a liaison to private landowners and assist the department in providing habitat management and technical assistance for conservation of species of greatest conservation need.

The WHIP program, administered by the USDA Natural Resources Conservation Service (NRCS), helps landowners create and enhance wildlife habitat on their property. NRCS and the department are partners in the implementation of the WHIP program. “We’ll help develop habitat plans and recommend ways to carry out management practices that create, restore and enhance fish and wildlife habitat,” explained Mary Beth Adler, one of the department’s new habitat specialists. “WHIP provides financial assistance in the form of cost share payments to enhance habitat on eligible land and also provides participants with technical assistance and educational materials for wildlife habitat needs. Our goal is to foster a positive public attitude towards wildlife, wildlife habitat and land stewardship.”

Wildlife may face new challenges in the coming years. But the Vermont Fish & Wildlife, NRCS, Coverts, and its other partners are gearing up to meet them.

For more information about WHIP, contact Dave Adams 879-2330 (Essex), Mary Beth Adler 885-8836 (Springfield) or Fred Schroeder 786-3879 (Rutland) or see the department’s Habitat Highlights newsletter available on line at www.vtfishandwildlife.com.

Public Meetings for Vermont’s Comprehensive Wildlife Conservation Strategy

July 12: Montpelier High School, Montpelier. 7-8:30p.m.
July 14: Burr and Burton Academy, 57 Seminary Ave. Manchester. 7-8:30p.m.

Public meetings will include information packets, a presentation on the CWCS, and a question and answer session. Copies of the CWCS will be available through our website beginning approximately July 6th. Comments and questions can also be submitted electronically at: www.vtfishandwildlife.com/SWG_home.cfm

SPEAK UP!
CSI:VT Fish Lab
by Jon Kart, CWCS Coordinator

Hurrying to a dependable Vermont trout stream, two anglers can’t wait to start their spring day. Wading to their favorite location, one of the anglers notices several small trout struggling to swim. Investigating further they notice that the fish start to swim erratically, whirling about. Soon the fish tire, lying on their sides, gasping rapidly. The anglers are concerned; they have never seen trout like this before.

Smooth as glass, the picturesque lake is a haven for many fish species. A lone bass fisherman notices hundreds of dead carp floating on the surface. Taking a closer look, he notices red sores on the carp.

The two scenarios above are hypothetical but could become a troublesome reality in Vermont. In both cases, anglers would likely report their findings to the Vermont Fish & Wildlife Department or the Vermont Department of Environmental Conservation. Both are responsible for investigating fish kills in the state.

Vermont Fish & Wildlife Department fish health biologists, Thomas Jones or Barbara Johnston, would respond to the scene, collecting potential evidence to establish a cause. Each scenario is an example of a disease that is of major concern to the department: Whirling Disease, a parasite, and Spring Viremia of Carp, a virus.

In 2002, Whirling Disease was first discovered in brook trout and brown trout from Vermont's Batten Kill River. For official confirmation of this disease in the Batten Kill River, samples were sent out-of-state.

Spring Viremia of Carp is a new disease. It was first discovered in a small lake in North Carolina in 1989 and has since spread to other parts of the United States. The disease is caused by a virus that affects carp and other cyprinid fish. The symptoms include a loss of equilibrium, which causes the fish to swim erratically and eventually die. The disease has a significant impact on the fish population and can also affect anglers who catch and eat the affected fish.

To control Spring Viremia of Carp, the Vermont Fish & Wildlife Department has implemented several measures, including the use of antiviral drugs and the quarantine of affected areas. These measures aim to prevent the spread of the disease and protect the state’s fish populations.

Continued on page 5
regulation of pesticides, habitat protection and active management under department-led programs. Partnerships with the Vermont Institute of Natural Science (VINS), National Wildlife Federation, Vermont electric utilities and private landowners, and the support of the general public were vital to these successes.

In the case of peregrines, a hacking (captive breeding) program was established. For osprey, electric utility companies helped erect nesting platforms. The loon benefited from water level stabilization during breeding season to avoid inundating nests, installation of artificial floating nests and public education. Careful monitoring of all three species was essential to assess and improve recovery efforts.

Populations of each of these birds have grown sufficiently for them to be removed from the Endangered Species List. That doesn’t mean they’ll be ignored from here out. Monitoring and management plans for each species will be ongoing. And, in the event that populations again decline, steps will be taken to prevent the need for re-listing.

**Lessons learned: Practice Smarter Wildlife Conservation**

Everyone working on these recovery projects could tell you that had we started earlier, recovery would have been much easier and cheaper. Unfortunately funding was limited. Thanks to our Congressional representatives, we now have a State Wildlife Grants program (SWG). Created in 2001, SWG provides money to every state to prevent species from becoming endangered (see related articles in this newsletter). In Vermont, SWG has funded more than 40 conservation projects to date.

“Recovering an endangered species is a milestone that every wildlife enthusiast can be proud of.”

- Craig McLaughlin -

“Recovering an endangered species is a milestone that every wildlife enthusiast can be proud of. Recovering three is a great achievement to celebrate,” said Craig McLaughlin, Wildlife Director for the Vermont Fish & Wildlife Department.

One of the best gifts we can give the peregrine, osprey and loon is to show that we’ve learned from the past. That we won’t wait until another species practically disappears before taking action. With the help of the SWG program we will keep more common species common.

**CSI:VT Fish Lab**

*Continued from page 4*

Disease to the United States. It was first discovered in 2002 on a North Carolina carp farm. Since then, it has been discovered in fish from a major carp kill in Cedar Lake, Wisconsin. Because of the severity of this disease, it is listed as one of the top five deadly viruses found in fish worldwide.

It takes two to three weeks for test results to return from out of state labs. This is a long, long time when diseases such as these are expected. Now, thanks to funding from the State Wildlife Grants program, the Vermont Fish & Wildlife fish health laboratory will acquire state-of-the-art genetic testing equipment.

*Continued on page 6*
CSI:VT Fish Lab

Continued from page 5

that is required to confirm many fish diseases.

The new testing procedure is called Polymerase Chain Reaction. “The PCR test is a fabulous invention,” said Jones. “One of the test components is produced from bacteria called Thermus aquaticus. This bacterium was first discovered in a hot spring in Wyoming’s Yellowstone National Park.” The PCR test is being used around the world with many applications, including but not limited to human diseases, evolutionary studies, genetic research, and criminology investigations.

Now it’s being used to help detect, prevent and control serious fish diseases, enabling biologists to more effectively conserve and manage fish. Both Johnston and Jones are excited about obtaining this new technology provided by the State Wildlife Grant initiative.

The State Wildlife Grants (SWG) program plays a vital role in efforts to conserve Vermont’s wildlife. Since 2001, SWG has funded more than 40 programs in Vermont including conservation research and recovery planning, terrestrial and aquatic habitat assessments, and the inventory and monitoring of rare and uncommon species.

Here is a list of current and ongoing SWG-funded projects.

- Bobcat habitat use and habitat assessment.
- Improving road/stream crossing structures to aid fish and other aquatic organisms.
- Statewide all-bird inventory (atlas).
- Statewide butterfly inventory (atlas).
- Lake Champlain deepwater forage fish inventory.
- Inventory for rare and uncommon non-game fish such as sculpin, stonecat, several species of redhorse, shiner and darter.
- Comprehensive inventories of State Wildlife Management Areas for amphibians, reptiles, invertebrates, non-game fish, birds, and mammals.
- Inventory and recovery planning for several species of rare tiger beetles.
- Public workshops to reduce the spread of invasive non-native fish sold as bait fish.
- Lake sturgeon inventory and recovery planning.
- Muskellunge inventory and recovery planning.
- Stream temperature and habitat improvement.
- Bicknell’s thrush inventory and habitat assessment.
- Research on the black-throated blue warbler.
- DNA-based fish health research.

Appendix I
Explanation of Legal Status and Information
Ranks used by the Nongame & Natural Heritage Program, Vermont Fish & Wildlife Department
Appendix I: Explanation of Legal Status and Information Ranks
Nongame & Natural Heritage Program
Vermont Fish & Wildlife Department

Legal Status
State Status per the Vermont Endangered Species Law (10 V.S.A. Chap. 123)
E: Endangered: in immediate danger of becoming extirpated in the state
T: Threatened: with high possibility of becoming endangered in the near future

Information Categories only; not established by this law
SC: Special Concern: rare; status should be watched
PE: Proposed for endangered
PT: Proposed for threatened

Federal Status As per the Federal Endangered Species Act (P.L. 93-205)
LE: Listed endangered
LT: Listed threatened

Natural Heritage Ranking: Informational categories only; not established by law. Developed by the Science Division of The Nature Conservancy.
State Ranks of Plants, Animals, and Natural Communities
State ranks are assigned by the Nongame & Natural Heritage Program based on the best available information. Ranks are reviewed annually. For bird species the ranks refer to breeding status only.
S1: Very rare, generally 1 to 5 occurrences believed to be extant and/or some factor(s) making it especially vulnerable to extirpation from the state
S2: Rare, generally 6 to 20 occurrences believed to be extant and/or some factor(s) making it vulnerable to extirpation in the state
S3: Uncommon, believed to be more than 20 occurrences and/or there is some threat to it in the state
S4: Apparently secure in state, often with more than 100 occurrences
S5: Demonstrably secure in state
SA: Accidental in state
SE: An exotic established in state
SH: Known from historical records only
SR: Reported from the state, but without persuasive documentation
SRF: Reported in error but this error persisted in the literature
SP: Possible in the state but no reported or documented records
SSYN: No longer considered a taxon in the state.
SZ: Not of practical conservation concern because there are no definable occurrences
SX: Extirpated from the state
SU: Status uncertain
?: Denotes provisional rank
Breeding Status (primarily birds) only for species which have distinct breeding and or non-breeding populations

B: Breeding status e.g. S1B is a very rare breeder
N: Nonbreeding status e.g. S1N is a very rare nonbreeder; and SZN is a migrant that occurs in an irregular, transitory, and/or dispersed manner

Global Ranks of Plants, Animal, and Natural Communities
Global Ranks are assigned by the international network of Natural Heritage Data Centers. The ranks are tracked by The Nature Conservancy and by The Natural Heritage Programs. They reflect the rarity and endangerment of species worldwide.

G1: Critically imperiled globally (on the order of 1-5 occurrences worldwide)
G2: Endangered globally (ca. 6-20 occurrences worldwide)
G3: Threatened globally: rare and/or local
G4: Apparently secure globally, though perhaps locally rare
G5: Demonstrably secure globally
T: Subrank for subspecies and varieties; 1-5 ranking similar to G ranks
Q: Questionable taxonomic assignment
?: Denotes provisional rank
NE: Exotic established in nation
GU: Status uncertain

</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>4.8 Will the project contribute a long term benefit to the public or to species with greatest unmet conservation needs? Does the project appear to have the potential for &quot;life&quot; after SWG funding ends? Is there a plan/process to &quot;market&quot; the project as a model or demonstration area once completed and/or will the information gathered contribute to long term conservation goals?</th>
</tr>
</thead>
<tbody>
<tr>
<td>(no long term relevance)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>4.9 Will the data from this project be demonstrably useful for updating Vermont's Comprehensive Wildlife Conservation Strategy?</th>
</tr>
</thead>
<tbody>
<tr>
<td>(No)</td>
</tr>
</tbody>
</table>
5. Social Impact  Max 30 points

5.1 Does the proposal bring traditional and/or nontraditional partners to the table? Does the project involve state and/or local decision-makers? Is there multi-partner involvement (federal, state, and local governments or agencies, businesses, private landowners, NGO’s, research institutions, citizens, etc)?

| partners not significant | 1 | 2 | 3 | 4 | 5 | (partners significant) |

5.2 Will the project be useful to other agencies and organizations? Can it serve as a model process or demonstration site?

| (not useful as model) | 1 | 2 | 3 | 4 | 5 | (very useful) |

5.3 Does the project have an educational component that will lead to increased appreciation, understanding, support, stewardship, of wildlife?

| (no education component) | 1 | 2 | 3 | 4 | 5 | (strong education component) |

5.4 Does the project have potential for widespread or statewide public/media appeal?

| (low appeal) | 1 | 2 | 3 | 4 | 5 | (high appeal) |

5.5 Does the project encourage public involvement in its implementation or use? Is it open for public use and enjoyment (where appropriate) and/or engage the full range of conservation interests (public and private sectors, traditional and non-traditional constituencies, etc)?

| (low public benefit) | 1 | 2 | 3 | 4 | 5 | (high public benefit) |

5.6 Does the project demonstrate multiple benefits? (Conservation and/or recreation and/or education; benefit terrestrial and aquatic species; consumptive and non-consumptive users, etc)

| (narrow benefit) | 1 | 2 | 3 | 4 | 5 | (multiple benefits) |

6. Other Factors  Max 35 points

6.1 What is the overall feasibility of the project?

| (infeasible as proposed) | 1 | 5 | 10 | (very feasible) |

6.2 Project timeliness: is the project ready or near-ready to implement? Will there be significant deliverables within the first fiscal year?

| (long start up required) | 1 | 5 | 10 | (project ready to go) |

6.3 Are project activities focused on achieving the stated goals and objectives? Does the project have clearly stated objectives, well designed procedures and realistically attainable results? (For research & inventory projects: Are sample sizes adequate? Is data analysis and utilization, and methods for sharing results included?)

| (activities not focused) | 1 | 5 | 10 | (activities focused) |

6.4 What is the capability of project personnel for completing the project (the applicant’s history with previous projects can be used to assess this criterion)?

| (Potential for success low) | 1 | 2 | 3 | 4 | 5 | (Potential for success high) |

Exotic Invasive & Pest Species

Introduction to Invasive Exotic and Pest Species......................... 1
Invasive Species Watch List for Vermont....................................... 3
DEC's Non-native Plant & Animal Species in Aquatic & Wetland Habitats in Vermont .......................................................... 7
Agency of Agriculture's Quarantine #3 Noxious Weeds................. 9
Introduction to Invasive Exotic and Pest Species

Invasive exotic and pest species are one of the most frequently noted problems impacting Vermont’s Species of Greatest Conservation Need (SGCN) and their habitats. Invasive species can literally overwhelm native species and their habitats forcing the natives out. Invasive plants such as Japanese knotweed, phragmites, and purple loosestrife can change soil composition, change water tables and disrupt insect cycles. They often lack food value that wildlife depend upon compared with the plants they've replaced. Some invasive animals prey heavily upon natives while others such as the alewife and zebra mussel out-compete natives for food and nutrients with significant impacts reverberating up and down food chains.

The problem of invasives isn't simply a local one. Each year the United States loses 1.7 million acres to the spread of these invasives and estimates of the total costs of invasive species in the United States amounts to more than $130 billion annually (Pimentel et al. 1999). About 42% of the species on the federal Threatened or Endangered species lists are at risk primarily because of non-indigenous species (Wilcove et al. 1998).

Some non-natives species are considered invasives or pests. Some are deemed beneficial (e.g. apple trees) while others are considered neutral (e.g. Queen Anne’s lace and goldfish). An invasive species is defined by the National Invasive Species Council (Executive Order 13112); http://www.invasivespecies.gov/ as a species that is:
1) Non-native (or alien) to the ecosystem under consideration; and,
2) Whose introduction causes or is likely to cause economic or environmental harm or harm to human health.

The national strategy to address invasive species encompasses four elements (US Forest Service 2004)
1) Prevention
2) Early detection and rapid response
3) Control and management
4) Rehabilitation and restoration

Strategies to address impacts from invasive exotic and pest species are noted here in each species conservation summary (Appendix A) and in the habitat, community, and landscape summaries (Appendix B). However, the world of invasive exotic control and eradication is a rapidly evolving one. This section of the CWCS report provides lists of invasive species maintained by state agencies and along with key resources that readers should check for more up-to-date information and expert assistance.
Vermont's Invasive Species

The three lists of invasive species currently maintained by the state were developed for different reasons and with different publics in mind. Combined they identify the most significant invasives in the state. They are:

Invasive Species Watch List for Vermont

Vermont Invasive Exotic Plant Committee
February 18, 2005

Introduction

This is a list of non-native plants that have some potential to become invasive in Vermont based on their behavior in northeastern states. Since not enough is known about the distribution or abundance of these species in Vermont, or their potential to become invasive in Vermont, we hope this list encourages people to observe, assess and report where these species occur and how rapidly they may be spreading.

About one-third of the plant species found in Vermont are not native to our state. Many of these introductions are beneficial and economically important (e.g. red clover, our state flower) and many others are neutral in their impact (e.g. mullein or Queen Anne's lace.) A small percentage of the non-native plants, about 8%, have the potential to create environmental and economic harm due to their ability to grow rapidly, profusely and widely. It is these non-native invasive plant species that the Vermont Invasive Exotic Plant Committee is monitoring.

Definition

An invasive species is defined by the National Invasive Species Council as a species that is
1) non-native (or alien) to the ecosystem under consideration and
2) whose introduction causes or is likely to cause economic or environmental harm or harm to human health. (Executive Order 13112; http://www.invasivespecies.gov/)

Invasive species can be plants, animals, and other organisms (e.g., microbes). Human actions are the primary means of invasive species introductions.

Watch List versus the Noxious Weed Quarantine

This Watch List is different from the Noxious Weed Quarantine Rule created in 2002 by the Vermont Agency of Agriculture, Food and Markets. The Watch List is intended for public information and as a way to enlist volunteers to monitor potentially harmful plants in Vermont. The Watch List has no regulatory force.

The Noxious Weed Quarantine Rule has the force of law. It was created to regulate the importation, movement, sale, possession, cultivation and/or distribution of 32 invasive plants. For more information about the Noxious Weed Quarantine Rule see www.state.vt.us/agric/invasive.htm. The rule plus additional information is also posted at www.uvm.edu/mastergardener/. Click the yellow circle at the bottom for Invasive Plant Info.
Purpose of the Watch List

The purpose of this Watch List is to alert and inform people about some plants that may become invasive in Vermont. We’ve included species known to be invasive elsewhere but their status in Vermont is uncertain. The listed plants are primarily those that may spread into Vermont’s natural habitats; this list does not include plants that may be pests of agricultural lands or disturbed habitats such as roadsides. Some of these plants are not yet here as far as we know. Others are here but no one knows how extensively they occur or whether they are spreading. We hope that by making this list public, people will be motivated to help track the occurrence, distribution and rate of spread of the listed plants throughout Vermont.

Criteria

For inclusion on the Watch List, a plant must meet at least #1 and #2, and either #3 or #4.

1. The taxon\(^1\) is nonindigenous\(^2\) to northeastern North America.
2. The taxon may negatively affect native species or natural communities.
3. In Vermont, the taxon has the potential, based on its biology and its colonization history in the northeast or elsewhere, for rapid and widespread dispersal and establishment over spatial gaps away from the site of introduction.
4. The taxon is acknowledged to be invasive in northeastern North America but its Vermont status is unknown or unclear. This may result from lack of field experience with the taxon or from difficulty in taxonomic determination.

Invasive Species Impacts

Invasive non-native species are the second greatest worldwide threat to native species and ecosystems after direct habitat destruction\(^3\). In the United States invasive non-native plants spread on public lands at the rate of 4,600 acres per day, or one-tenth the size of an average Vermont town.\(^4\) Invasive non-native plants can displace native species, disrupt ecosystem relationships, degrade wildlife habitat, impede recreation and cause economic damage to forests, agricultural crops and other managed lands. Invasive species cost the American public an estimated $138 billion each year\(^5\) and negatively impact about 42% of the plant and animal species listed by the Federal government as threatened or endangered\(^6\).

---

\(^1\) A taxon can be a species, a subspecies or variety
\(^2\) Indigenous means native to an area.

What You Can Do

We encourage you to identify, observe, map or measure, and report on the status of any of these plants you find in your vicinity. By making this Watch List public, we hope that people will pay more attention to the plants around them, help in the effort to collect data and watch these species for signs of invasiveness. A more comprehensive list of plant species that can become invasive throughout New England is on the website of the Invasive Plant Atlas of New England (IPANE) at [http://invasives.eeb.uconn.edu/ipane/](http://invasives.eeb.uconn.edu/ipane/).

Please send us, the Vermont Invasive Exotic Plant Committee, information on these plants and consider becoming a volunteer for IPANE (see box on the following page.)
To report invasive non-native terrestrial plants
Kathy Decker, Vermont Department of Forests, Parks and Recreation

About VTIEPC
The Vermont Invasive Exotic Plant Committee is comprised of representatives from state and federal government, non-profit organizations, private industry, and concerned individuals. The Committee meets semi-annually to assemble and disseminate information about invasive exotic plants. The goal of the Committee is to “provide coordination and guidance on invasive exotic plant issues so as to protect natural communities, native species, agricultural and forestry interests, and human use and enjoyment of Vermont’s natural resources.”

About IPANE
The Invasive Plant Atlas of New England’s (IPANE) mission is to create a comprehensive web-accessible database of invasive and potentially invasive plants in New England that will be continually updated by a network of professionals and trained volunteers. The database will facilitate education and research that will lead to a greater understanding of invasive plant ecology and support informed conservation management. An important focus of the project is the early detection of, and rapid response to, new invasions. To learn how to volunteer go to http://invasives.eeb.uconn.edu/ipane/.

Quarantine #3 Noxious Weeds

Vermont Department of Agriculture, Food & Markets
April 22, 2002

Vermont noxious weed quarantine was created in order to regulate the importation, movement, sale, possession, cultivation and/or distribution of certain invasive plants. These plants either pose a threat the Vermont environment or are already negatively impacting waterways and natural areas in the state. Many of these plants are becoming such a problem that there is no alternate prevention method. This rule will also prevent plants not yet found in Vermont from being introduced, and will protect the state from the many environmental, agricultural, recreational, and/or economical problems associated with their presence.

For questions and comments related to Vermont’s Noxious Weed Quarantine Rule go to www.vermontagriculture.com/noxiousweeds.PDF, or contact:

VT Department of Agriculture, Food & Markets
Plant Industry Division
116 State St., Drawer 20
Montpelier, VT 05620-2901
802-828-2431
www.state.vt.us/agric/

Designated Noxious Weeds

(A) Class A Noxious Weeds.
(1) All weeds listed in 7 C.F.R. 360.200 as amended, which is hereby incorporated by reference including subsequent amendments and editions.
(2) Cabomba caroliniana (fanwort)
(3) Egeria densa (Brazilian elodea)
(4) Hydrilla verticillata (hydrilla)
(5) Hygrophila polysperma (E. Indian hygrophila)
(6) Myriophyllum aquaticum (Vell.) Verde. (Parrot feather)
(7) Myriophyllum heterophyllum (variable-leaved milfoil)
(8) Salvinia auriculata (giant salvinia)
(9) Salvinia biloba (giant salvinia)
(10) Salvinia benggee (giant salvinia)
(11) Salvinia molesta (giant salvinia)
(12) Vincetoxicum hirundinaria Medikus. (pale 62 swallow-wort)

(B) Class B Noxious Weeds.
(1) Aegopodium podagraria L. (goutweed)
(2) Ailanthus altissima (tree-of-heaven)
(3) Alliaria petiolata (A. officinalis) (garlic mustard)
(4) Butomus umbellatus (flowering rush)
(5) Celastrus orbiculatus Thunb. (Oriental bittersweet)
(6) Fallopia japonica (Polygonum cuspidatum) (Japanese knotweed)
(7) Hydrocharis morsus-ranae L. (frogbit)
(8) Lonicera × bella (Bell honeysuckle)
(9) Lonicera japonica (Japanese honeysuckle)
(10) Lonicera maackii (Amur honeysuckle)
(11) Lonicera morrowii (Morrow honeysuckle)
(12) Lonicera tatarica (Tartarian honeysuckle)
(13) Lythrum salicaria (purple loosestrife)
(14) Myriophyllum spicatum (Eurasian watermilfoil)
(15) Nymphoides peltata (Gmel.) (yellow floating heart)
(16) Phragmites australis (common reed)
(17) Potamogeton crispus L. (curly leaf pondweed)
(18) Rhamnus cathartica (common buckthorn)
(19) Rhamnus frangula (glossy buckthorn)
(20) Tripterygium wilfordii (water chestnut)
(21) Vincetoxicum nigrum L. (black swallow-wort)
Appendix L
Plans & Planning Processes
Impacting Vermont Wildlife
L. Plans & Planning Processes Impacting Vermont Wildlife

The Comprehensive Wildlife Conservation Strategy has not tried to reinvent wheels in its attempt to conserve Vermont's wildlife. Rather it strives to connect existing programs with wildlife in need and with the people and organizations wishing to help. Conservation strategies found in this report list potential funding sources and potential partners to help readers connect with others interested in similar efforts. However, this is only the tip of the proverbial iceberg when it comes to plans and planning process that can impact Vermont's wildlife. The following list can further orient and direct (though hopefully not overwhelm) interested parties. The list is clearly incomplete as there are too many local plans as well as numerous organizations spearheading public/private collaborations to mention here.
